GROUNDWATER LEVELS IN SOUTH CAROLINA, 2011–2018

by

Andrew Wachob, Joshua M. Williams, Jess McDaniel, Brooke Czwartacki, and Scott V. Harder

ABSTRACT

This report presents water-level hydrographs from 168 South Carolina Department of Natural Resources groundwater monitoring wells for the years 2011 through 2018. Most wells are located in the Coastal Plain physiographic province, but a few wells are located in the Piedmont or Blue Ridge provinces. The hydrographs provide insight into recent and long-term water-level trends in the major aquifers of South Carolina.

No single water-level trend was apparent in all wells of any given aquifer. Groundwater levels throughout much of the state were relatively low during most of 2011 and 2012 because of a severe, statewide drought. Most aquifers, however, recovered quickly in 2013. In confined Coastal Plain aquifers, many wells located downdip from recharge areas showed declining water levels from year to year. Three-quarters of the monitoring wells having data prior to 2011 recorded all-time lowest water levels during the years 2011 through 2018. In recent years, seasonal water-level drawdowns have become noticeably larger in many areas owing to increased groundwater pumping, primarily for agricultural irrigation.

INTRODUCTION

The South Carolina Department of Natural Resources (SCDNR) maintains a statewide network of monitoring wells to facilitate the routine collection of groundwater-level data, which help inform water-resource assessments, management, and planning. Groundwater-level data are used to identify short- and long-term changes in groundwater levels and aquifer storage due to changes in withdrawals, recharge rates, and climatic conditions; to construct potentiometric maps of major aquifers; to calibrate groundwater flow models; and to determine regional hydraulic gradients and groundwater flow rates and directions.

At the end of 2018, the SCDNR groundwater monitoring network consisted of 166 wells at 88 monitoring sites, measuring water levels in 9 major aquifers. In more than three quarters of those wells, water levels are measured hourly with automated data recorders (ADRs); the remaining wells are measured manually, typically four to six times per year. Almost half of the network wells have measurements dating back at least 20 years, and 55 wells were added to the network between 2011 and 2018.

This report presents groundwater-level data collected from 168 SCDNR monitoring wells during the years 2011 through 2018. Water-level hydrographs are presented for each well, grouped by aquifer, in the appendices. The wells included in this report are listed by county in Table 1, which also includes descriptive well locations and aquifer designations. A map showing the location of each well is presented on the Plate.

In addition to presenting recent water-level data, this report includes a description of recent water-level trends

seen in each aquifer. For several SCDNR monitoring wells having many years of water-level data prior to 2011, period-of-record hydrographs are included to inform a brief review of long-term trends in groundwater levels.

PREVIOUS WATER-DATA REPORTS

This is the fourth in a series of reports documenting groundwater-level data collected from the SCDNR monitoring network, and closely follows the format of *Ground-Water Levels in South Carolina, 2006–2010* (Harder and others, 2012), which presents groundwater-level data from 109 wells at 57 sites in South Carolina. Agerton and others (2007) contains water-level data collected from 69 wells during the years 2000–2005, and includes specific conductance data from one well at Edisto Island. Harwell and others (2004) documents water-level data collected from 56 wells during the period from 2000 through 2001 and includes specific conductance data from two wells in Charleston and Colleton Counties. Waters (2003) is the most extensive compilation of historical South Carolina groundwater-level data, presenting hydrographs of 16 Piedmont province wells and 266 Coastal Plain province wells, ranging from 6 to 50 years, with about one-third of the record sets spanning periods greater than 20 years. Gellici and others (2004) published selected groundwater data illustrating effects of the 1998–2002 drought.

SCDNR also publishes potentiometric maps for the major Coastal Plain aquifers on a rotating basis. Since 2016, SCDNR has used the hydrogeologic framework of Gellici and Lautier (2010) to identify aquifers for potentiometric mapping. Groundwater-level data collected in

2016 were used to produce potentiometric maps for the McQueen Branch, Crouch Branch, and Floridan/Gordon aquifers (Wachob and others, 2017), and potentiometric maps of both the Floridan and Gordon aquifers were produced from data collected in 2018 (Czwartacki and others, 2019).

Prior to 2015, potentiometric maps were produced for the major aquifers as defined in the hydrogeologic framework of Aucott and others (1987). Potentiometric levels for the Middendorf aquifer in 1996, 2001, 2004, 2009, 2011, and 2014 were presented by Hockensmith and Waters (1998), Hockensmith (2003a), Hockensmith (2008a), Hockensmith (2012a), Hockensmith and others (2013a), and Wachob (2015), respectively. Potentiometric levels for the Black Creek aquifer in 1995, 2001, 2004, 2009, 2012, and 2015 were presented by Hockensmith (1997), Hockensmith (2003b), Hockensmith (2008b), Hockensmith (2012b), Hockensmith and others (2013b), and Wachob and Czwartacki (2016), respectively. Seasonal potentiometric maps for the Floridan aquifer for the period 1991–1993 are documented in Gawne (1994), and Floridan aquifer levels for 1998, 2004, 2010, 2013, and 2018 were published by Hockensmith (2001), Hockensmith (2009), Hockensmith and others (2013c), Wachob and others (2014), and Czwartacki and other (2019), respectively.

WELL-NUMBERING SYSTEM

Wells are identified by a unique county well number, which consists of a three-letter county name abbreviation and a four-digit number sequentially assigned by SCDNR. For example, HAM-0050 represents the fiftieth well inventoried by SCDNR in Hampton County.

DATA COLLECTION

The groundwater-level data presented in this report were collected by SCDNR from monitoring wells in the SCDNR network. For two wells, data collected by the U.S. Geological Survey (USGS) are included to supplement SCDNR data in order to provide a more complete record of water-level data. Groundwater levels are presented in feet (ft) above or below land surface.

Land-surface elevations at well sites were obtained from surveys using USGS and South Carolina Geodetic Survey benchmarks or from lidar-derived land surface elevation data. Well-site elevations reference the North American Vertical Datum of 1988 (NAVD88) and are reported to the nearest foot in this document. Geographic coordinates of wells are reported as latitude and longitude in decimal degrees and were determined with the Global Positioning System (GPS) using the North American Datum of 1983 (NAD83).

Measurements and sensor settings are made relative

to a specified measurement point, and the data-collection methods used generally follow those of USGS (Cunningham and Schalk, 2011).

Manual Measurements

Manual measurements typically are made with electric tapes, which are capable of an accuracy of 0.01 ft. However, visibility, thermal expansion and contraction, and tape sinuosity diminish measurement accuracy in field conditions. Accuracies, therefore, are assumed to be no better than 0.05 ft in practice. Less accuracy is likely where depth to water is greater than 100 ft.

Flowing artesian wells are manually measured with 0–30, 0–60, or 0–100 psi (pounds per square inch) range Bourdon-type pressure gages. The gages are calibrated annually by a commercial testing laboratory and are rated to 0.25 percent of their respective measurement ranges. In practice, accuracy will be diminished by errors from gage-zero adjustment, parallax, readings near the extremes of gage range, and mechanical degradation subsequent to calibration. Measured water pressure is converted to static water level above land surface, in ft, by multiplying the water pressure, in psi, by 2.31. Water levels determined from the 30, 60, and 100 psi gages are assumed to be accurate to 0.4, 0.5, and 0.8 ft, respectively.

Automated Measurements

Automated monitoring stations utilize pressure transducers whose readings are logged hourly and calibrated to manual measurements. Pressure transducers measure the height of water above a semiconductor strain gage: electrical resistance to an input voltage and, therefore, voltage output changes as varying water pressure deforms the crystalline lattice of the gage's silicon diaphragm (piezoresistive effect). There is a near-linear correlation between the sensor's pressure range and output-voltage range, and the height of water above the gage is computed from the voltage measurement.

Most pressure transducers currently used by SCDNR have a range equivalent to 0–66 ft (0–20 meters) and accuracy and resolution of less than 0.07 ft and 0.01 ft, respectively. In four wells having large water-level variations, transducers having a range equivalent to 0–98 ft (0–30 meters) are used. Two Piedmont wells are equipped with transducers having a range equivalent to 0–16 ft (0–5 meters). Because these transducers are not vented to the atmosphere and require barometric compensation to determine water level, hourly barometric data are collected at strategic sites for correction purposes.

During each site visit, the sums of the transducer measurement (depth above probe) and corresponding taped measurement (depth to water) are compared to evaluate transducer performance. If the sum of measurements is

found to differ by 0.20 ft or more from previous measurements, a potential instrument fault is suspected, but no record correction is applied. When the specifications are exceeded repeatedly, either the instrument is recalibrated or instrument failure is confirmed. If failure is confirmed, the transducer is replaced, and the associated water-level data are excluded from the record.

Data Storage and Quality

Logged measurements are stored in both raw-data and processed-data tables. The raw-data table contains uncorrected hourly measurements and reflects the readings and the performance of various sensors as they were originally stored in data loggers. Raw data are stored mainly “as is” and are archived at SCDNR for insight into hardware conditions and for quality assurance. Processed data are corrected for barometric pressure (where appropriate), converted from depth above the sensor to feet below or above land surface, and are winnowed of measurement anomalies and hardware failures. The winnowed data principally consist of spikes caused by lightning or electromagnetic interference and of measurements characteristic of hardware faults.

PRESENTATION OF WATER-LEVEL DATA AND STATISTICS

Appendices A–G present groundwater-level hydrographs and groundwater-level statistics for wells in the SCDNR groundwater monitoring network having some water-level data during the years 2011 through 2018. Each appendix represents one aquifer and contains water-level data for SCDNR wells screened in or open to that aquifer.

Each hydrograph shows water levels measured during the years 2011 through 2018. When sufficient ADR data are available, the hydrographs show average daily water levels as continuous lines. Manual water-level measurements are not shown if ADR data are available for the same date, but manual measurements are presented (as small open circles) on the hydrograph during times when average daily water levels are unavailable. For wells having only manual measurements throughout the eight-year period, individual data points are connected with dashed lines, as a visual aid to help identify data points. On these graphs, the dashed lines are not meant to suggest specific water-level behavior between measurements.

For each well equipped with an ADR, the appendices include a table showing the monthly and yearly minima (highest average daily water levels), maxima (lowest average daily water levels), and means for each year 2011 through 2018. Average daily water levels are calculated only for those days having 17 or more hourly measurements. Monthly minima, maxima, and means are calculated for each month having 14 or fewer days of missing

record; and yearly minima, maxima, and means are calculated for each calendar year having 10 or more months of record. No statistics are calculated for wells that are only manually measured owing to the relatively small number of data values available for such wells. Water-level data from the SCDNR monitoring network, including all data presented in this report, are available through the SCDNR website¹.

The information presented for each well in the appendices includes a period-of-record maximum and minimum water level. The highest and lowest water levels presented for each well only consider data collected through the year 2018; any record high or low water level measured after 2018 is not included in this report. The period of record listed for each well indicates the range of dates for which water levels have been measured; a period of record indicating data collection “through 2018” means data collection was still ongoing into the year 2019.

HYDROGEOLOGIC FRAMEWORK

The hydrogeologic framework and nomenclature of Coastal Plain aquifers used in this report is that of Gellici and Lautier (2010), which divides the Coastal Plain sedimentary sequence into eight major aquifers, which, in ascending order, are the Gramling, Charleston, McQueen Branch, Crouch Branch, Gordon, Middle Floridan, Upper Floridan, and surficial aquifers (Fig. 1). Water also exists within the crystalline rock beneath the sedimentary aquifers, but in the Coastal Plain this aquifer is rarely used. In the Piedmont and Blue Ridge regions of South Carolina, however, the crystalline-rock aquifer is the primary source of groundwater for most users.

The Gramling aquifer is the basal aquifer of the Coastal Plain, sitting on basement rock and occurring primarily only in the lower half of the Coastal Plain. The Gramling aquifer consists of unconsolidated to semi-consolidated interbedded quartz sand, clayey sand, silt, and clay, and reaches a thickness of 1,000 ft at Hilton Head Island in Beaufort County.

Like the Gramling aquifer, the Charleston aquifer occurs only in the lower half of the Coastal Plain. It is believed to be hydraulically connected to the overlying McQueen Branch aquifer in middle part of the Coastal Plain, but downdip, the two aquifers are separated by clay beds up to 200 ft thick. The Charleston aquifer consists of unconsolidated fine to very-coarse quartz sand, clayey sand, and clay, and reaches a maximum thickness of 300 ft in Jasper County. The Charleston aquifer is an important source of water for deep public-supply and industrial wells in the Charleston County area.

The McQueen Branch aquifer is a late Cretaceous-age aquifer extending over most of the Coastal Plain. The aquifer, which consists primarily of interbedded quartz sand and clay, outcrops along the Fall Line and reaches its

1 <http://hydrology.dnr.sc.gov/publications.html>

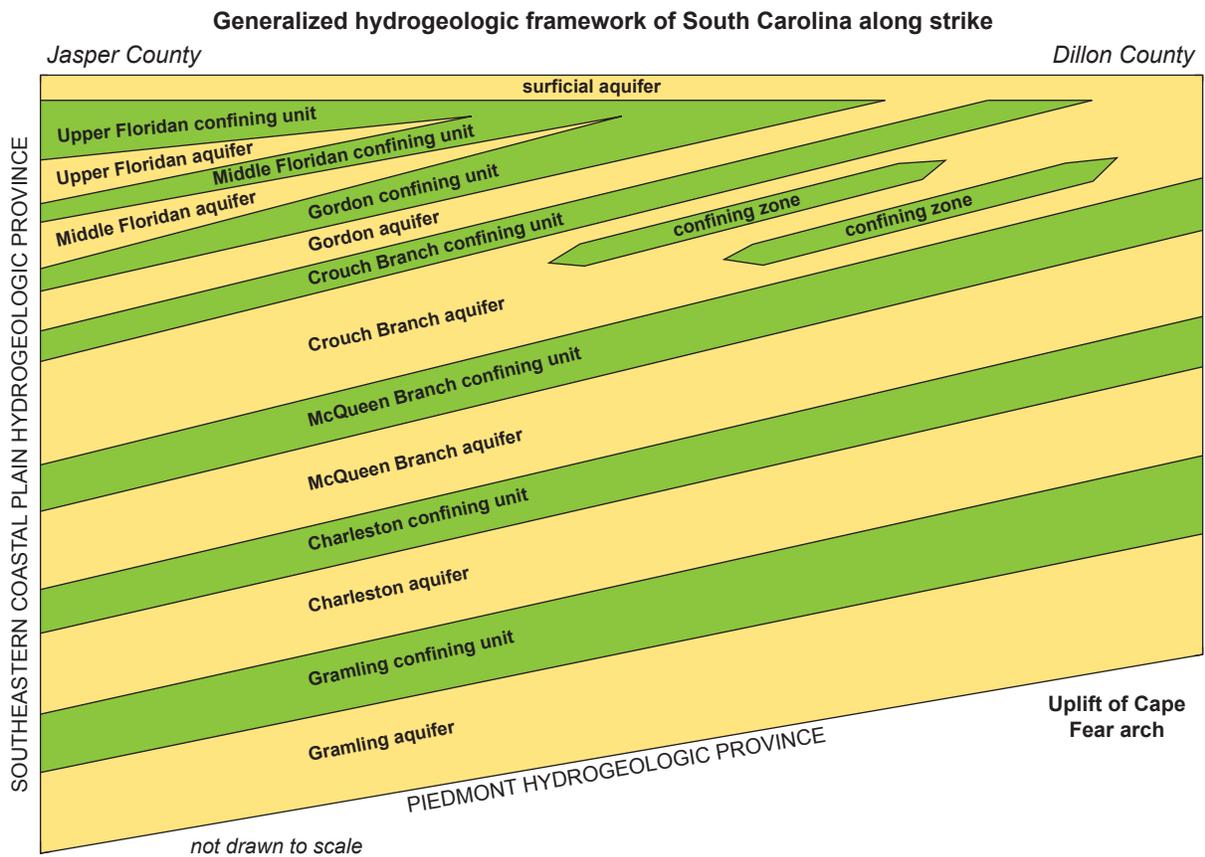

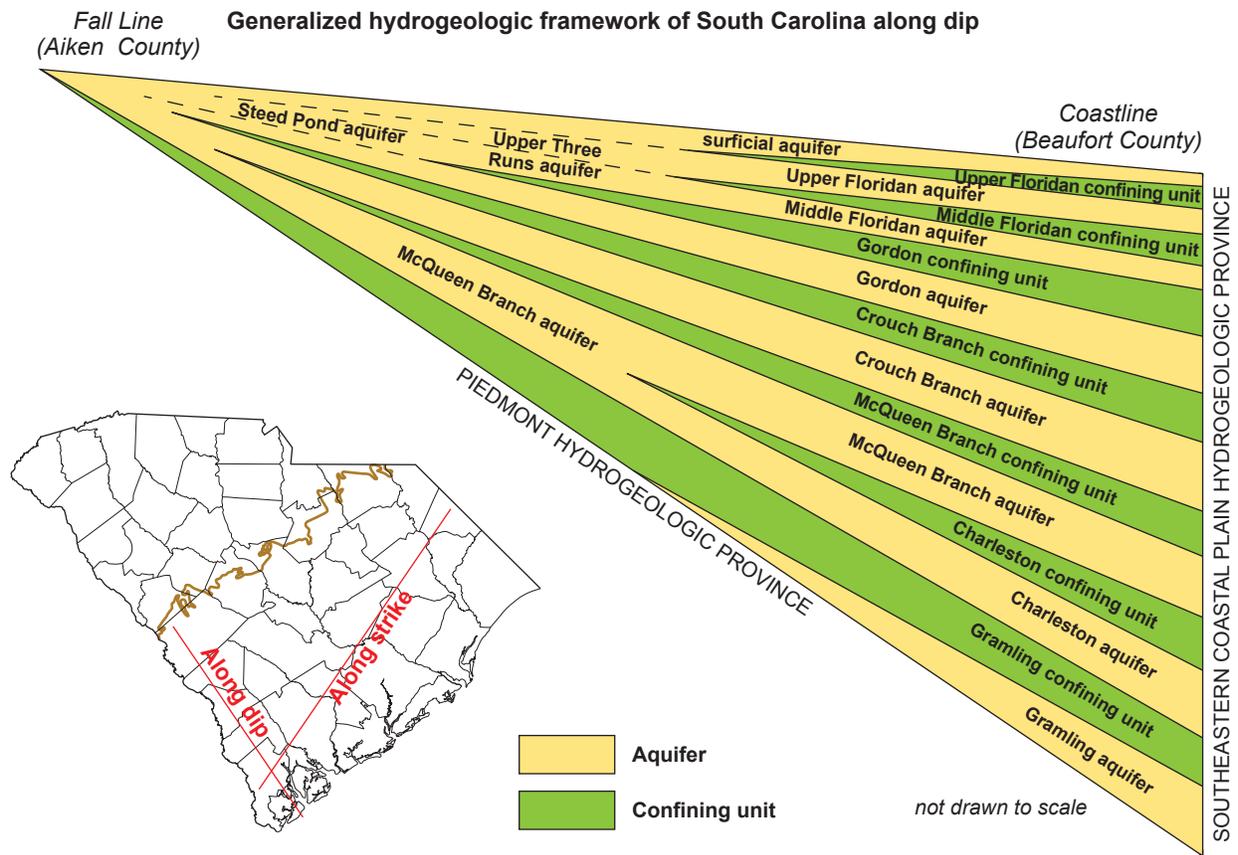

Figure 1. Generalized hydrogeologic framework of the South Carolina Coastal Plain.

maximum thickness of 350 ft in Barnwell County. In updip areas, the aquifer is composed of unconsolidated medium to very-coarse grained sand interbedded with clay lenses; downdip, it becomes very fine grained. The McQueen Branch aquifer is an important source of water for many public, industrial, and agricultural users throughout much of the Coastal Plain.

The Crouch Branch aquifer is the uppermost Cretaceous-age aquifer, consisting primarily of interbedded quartz sand and occurring over most of the Coastal Plain. Across its extent, the lithology and texture of the various formations that compose the Crouch Branch aquifer change, both laterally and vertically, owing to different depositional settings. The Peedee Formation, for example, consists of mostly coarse-grained quartz sand in the western part of the Coastal Plain, but transitions to fine-grained sand, clay, and marl in the east. In general, clay beds in Cretaceous formations are more prominent in the eastern part of the Coastal Plain, where they are sufficiently thick and continuous enough to divide the Crouch Branch aquifer into three aquifer zones; it is unknown, however, if these zones are hydraulically connected or isolated from each other. Like the McQueen Branch aquifer, the Crouch Branch aquifer is an important source of water for many public, industrial, and agricultural users throughout much of the Coastal Plain.

The Gordon aquifer is the lowermost Tertiary-age aquifer, occurring throughout the western and central parts of the Coastal Plain and overlying the Crouch Branch confining unit. The Gordon aquifer consists of several formations that are hydraulically connected. In its updip half, it consists primarily of siliciclastic sediments, whereas in its downdip half, it consists of both siliciclastic and carbonate sediments. Near Aiken County, the confining beds of the Gordon aquifer thin, allowing a hydraulic connection with the overlying Tertiary-age aquifers, forming the Steed Pond aquifer. In this report, wells open to the Steed Pond aquifer are considered to be part of the equivalent downdip Gordon aquifer.

The Middle Floridan aquifer occurs in much of the area west of the Santee River. Near its updip limit, the aquifer consists of unconsolidated quartz sand and clay of middle Eocene age; downdip, the Middle Floridan aquifer is predominately carbonate. The Upper Floridan aquifer occurs in South Carolina only in the westernmost quarter of the Coastal Plain. In the updip half of this area (Aiken, Barnwell, Bamberg and north Allendale Counties), the aquifer consists primarily of unconsolidated quartz sand and clay of late Eocene age. In the downdip half of this area (Allendale, Hampton, Jasper, and Beaufort Counties), the aquifer consists primarily of limestone. In the southernmost part of South Carolina, the Upper Floridan aquifer is very productive, and it is heavily used as a water source for irrigation, public supply systems, industries, and households. Where both aquifers occur in Aiken and

Barnwell Counties, the Upper and Middle Floridan aquifers are generally hydraulically connected, forming an aquifer referred to as the Upper Three Runs aquifer. In this report, wells open to the Upper Three Runs aquifer are assigned to either the Upper Floridan or Middle Floridan aquifer.

In the Coastal Plain, the surficial aquifer is present throughout most of the lower Coastal Plain and more sporadically in the middle Coastal Plain, where it is composed primarily of sand, shell, and clay, is generally less than 40 ft thick, and is the water-table aquifer. In the Blue Ridge and Piedmont, the surficial aquifer consists of porous materials overlying the fractured crystalline-rock aquifer system. Saprolite, the residual material from the weathering of bedrock, forms the most geographically extensive surficial unit above the Fall Line. Saprolite typically is 35 to 100 ft thick; but it is thin to absent in some mountainous areas and well over 100 ft in some lower areas, and is usually rich in clay, except where the parent rock is mainly quartz. Saprolite is the main source of groundwater storage in the region and the main source of groundwater in the underlying crystalline-rock aquifer. Where the saprolite is thick, water levels usually respond slowly to precipitation and drought because the low permeability of clay inhibits recharge and discharge.

The crystalline-rock aquifer consists of intrusive-igneous and metamorphic rock that transmits groundwater through fractures and faults. It is exposed or thinly covered in the Piedmont and Blue Ridge physiographic provinces, where it is the principal source of groundwater, but also extends beneath the Coastal Plain, where it is rarely used owing to greater permeability and water availability in the overlying sedimentary rock. The crystalline-rock aquifer contains a complex network of fractures, sparse in some areas and dense in others, especially along fault zones. The size, number, and extent of fractures diminish with increasing depth, and most crystalline-rock wells are less than 400 ft deep.

GROUNDWATER-LEVEL TRENDS

In this report, the term “recent trend” refers to a short-term water-level pattern spanning a few months or years and which is noticeable on the 2011–2018 hydrographs. Examples include changes in the magnitude of seasonal water-level fluctuations or changes in yearly maximum or minimum water levels. Although most trends are toward lower water levels over time, some wells may show increasing water levels. Short-term trends often result from unusual weather events, such as droughts, or significant changes in groundwater pumping rates. A severe, state-wide drought during 2011–2012 reduced aquifer recharge, resulting in lower groundwater levels in many wells and in all aquifers.

Seasonal fluctuations in groundwater levels are evident on many hydrographs, with high levels generally occurring during the late winter and early spring months (February–May) and with lows occurring most often during the late summer and fall months (September–December). This seasonal pattern is common in wells throughout the state, as storage in aquifers usually is reduced during the warmer growing seasons when evapotranspiration rates are high, and then recharged during the cooler dormant seasons when evapotranspiration rates are low. Increased groundwater pumping, particularly for agricultural irrigation, during late spring through early fall can significantly increase the magnitude of seasonal fluctuations.

In updip areas, near an aquifer’s recharge zone, long-term water-level trends—patterns that continue for many years or decades—are most often indicators of recent long-term climatic conditions (extended wet or dry periods). Farther downdip, in confined aquifers away from recharge areas, long-term water-level trends are primarily anthropogenic and associated with years of groundwater

withdrawals at rates exceeding an aquifer’s recharge rate. Long-term groundwater-level declines seen in monitoring wells indicate reductions in aquifer storage that are likely occurring throughout a widespread area.

Crystalline-Rock Aquifer

Recent water-level trends in the crystalline-rock aquifer

From 2011 through 2018, water levels were measured in 14 wells completed in the crystalline-rock aquifer (Fig. 2 and Appendix A). With a few exceptions, seasonal fluctuations were observed on the hydrographs, with high water levels occurring primarily from February–May and lows from September–December. Several wells, such as CRK-0074, GRV-3342, and LRN-1706, display less seasonality in their hydrographs, especially during droughts.

Water-level fluctuations in those wells ranged from about 2 to 22 ft during the eight-year period, with maximum yearly fluctuations typically ranging from 2 to 6 ft.

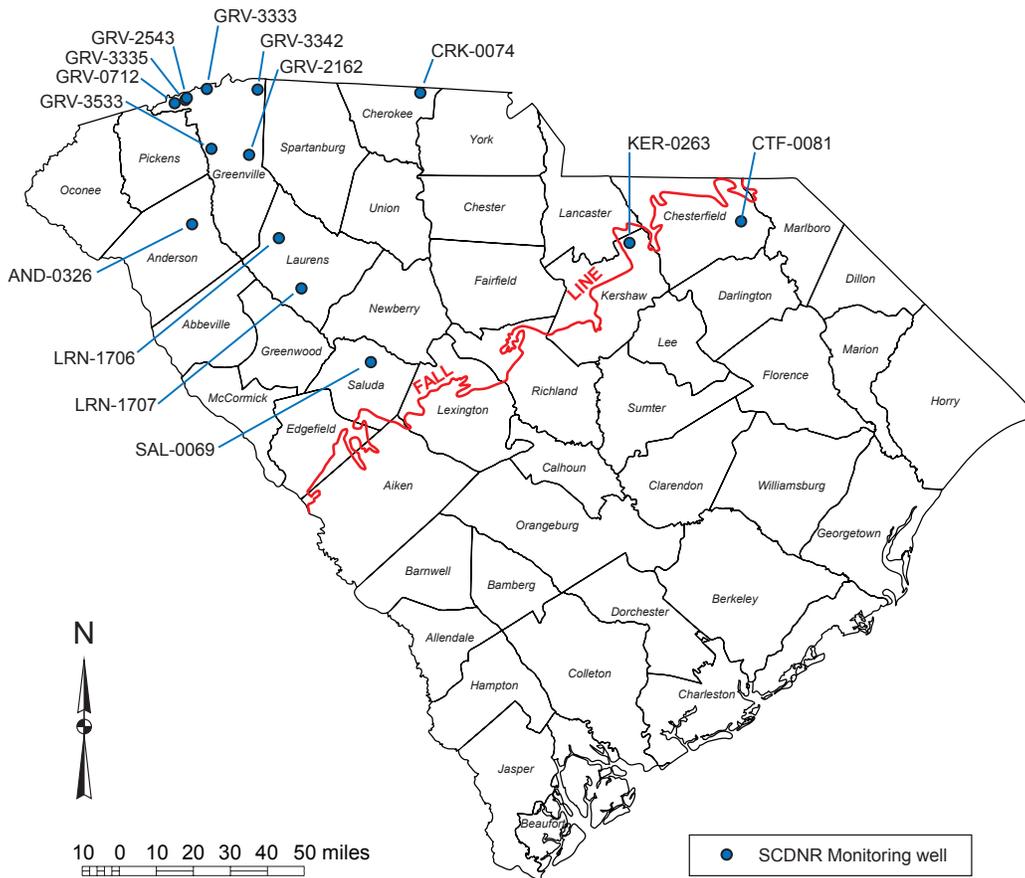

Figure 2. Map showing locations of crystalline-rock aquifer monitoring wells.

Well SAL-0069 showed the greatest overall water-level fluctuation and showed the greatest single-year water-level change, rising more than 16 ft in 2013, and rising or falling more than 10 ft in three other years. The water level in GRV-0712 also showed significant seasonal variations, fluctuating almost 10 ft in 2011, 8 ft in 2015, and more than 11 ft in 2016.

All wells were impacted by the 2011–2012 drought, but the severity and duration of the resulting water-level decline varied widely; and by 2014, water levels had generally recovered from the drought. Another period of dry weather beginning in late 2016 resulted in most wells showing below-normal springtime recoveries in 2017, although a few wells showed little or no evidence of drier weather that year.

During the eight years from 2011 through 2018, 7 wells recorded their lowest levels between late 2011 through early 2013, and 5 wells had their lowest levels in late 2016. Five of the 14 wells completed in the crystalline-rock aquifer also reached record-low water levels

during this period (Table 2), but four wells reached record-high water levels (Table 3).

Long-term water-level trends in the crystalline-rock aquifer

Each of the 14 crystalline-rock monitoring wells has from 16 to 25 years of water-level data. Over the course of those data-collection periods, most wells show no overall trend of decreasing or increasing water level. Two wells, LRN-1707 (Fig. 3) and GRV-0712 (Fig. 4), have a general trend of decreasing water levels, with each well showing an overall decline of about 3 ft since the early 2000s. Only one well, GRV-2162, shows a general trend toward higher water levels (Fig. 5). This increase is not gradual, however, as most of the gain occurred in the first half of 2013, during which the water level rose about 7 ft. Since late 2013, water levels have remained consistently higher than in the years before 2013.

Table 2. Recent record-low water levels in the crystalline-rock aquifer

Well	Previous record low (Date)	New record low (Date)	Difference (ft)

Surficial Aquifer

Recent water-level trends in the surficial aquifer

During the years 2011–2018, water levels were regularly measured in 11 SCDNR wells completed in the surficial aquifer (Fig. 6 and Appendix B). All but one well (ALL-0372) showed water-level fluctuations ranging from 2 to 9 ft, with maximum yearly fluctuations generally between 2 and 6 ft. Water levels in ALL-0372 had a range of 15.1 ft and a maximum one-year change of 11.4 ft.

Water levels in shallow aquifer wells tend to vary in direct response to precipitation events and climatic conditions. All wells for which data were recorded during the 2011–2012 drought show noticeably lower water levels during those years; and many wells show significant, rapid water-level rises as a result of major rainfall events associated with tropical storms in late 2015, 2016, and 2017.

Seasonal fluctuations are evident on most of the hydrographs, with high water levels typically occurring

from February–May and lows from September–December. Seasonal fluctuations are generally not seen in well GRV-3341, whose water levels vary more smoothly and in response to longer term weather events, such as the 2011–2012 drought, probably because the well is screened in relatively deep saprolite.

Long-term water-level trends in the surficial aquifer

Four of the six wells having water-level data prior to 2011 set new record lows during 2011–2018 (Table 4), breaking previous record lows set during the 2007–2009 drought. A fifth well (GRV-3336) recorded water levels in 2016 lower than those of the 2007–2009 drought, but water levels were not as low as its record minimum set in 2002. Only one well having water-level data prior to 2011 set a new record high water level during 2011–2018 (Table 5). Each drought during the past 20 years resulted in noticeably lower water levels (where data are available); but after each drought, water levels quickly recovered to pre-drought conditions. No long-term water-level declines or increases are seen in these wells.

Gramling and Charleston Aquifers

Recent water-level trends in the Gramling and Charleston aquifers

During some or all of the eight years from 2011 through 2018, water levels were measured in 6 wells completed in the Gramling aquifer, Charleston aquifer, or Gramling confining unit (Fig. 7 and Appendix C). All five wells monitored prior to the year 2011 reached record-low water levels during 2011–2018 (Table 6), and none had record-high water levels during those years. All but one well (BFT-2055) showed generally decreasing water levels during the eight-year period. Owing to its great depth and to lack of development by water users, the Gramling and Charleston aquifers generally experience only small seasonal water-level fluctuations and show little response to drought.

In eastern South Carolina, the water level of the Gramling aquifer at Myrtle Beach (HOR-0973) dropped about 3 ft from early 2012 through 2015; and in southern Marion County (MRN-0078), it steadily declined 9 ft from early 2012 to early 2018. At Little Pee Dee State Park, in Dillon County, the water level of the Gramling confining unit, monitored in DIL-0171 since mid-2014, shows little seasonal variation and is steadily decreasing by about 1 ft per year. In western South Carolina, the water level of the Gramling confining unit in Allendale County (ALL-0348) shows small seasonal fluctuations of generally less than 1 ft, and shows a minor downward trend resulting in an overall decline of about 1 ft from 2011 through 2018.

In Jasper County, water levels in the Charleston aquifer (JAS-0426) fluctuate as much as 3 ft during some years, but very little in other years. Overall, there is a

general trend toward lower water levels, particularly after 2015, with a decline of almost 1 ft per year.

Of the six deep monitoring wells, BFT-2055, at Hilton Head Island, is something of an anomaly. Unlike the other wells, BFT-2055, which is screened in both the Gramling and Charleston aquifers, not only shows large (up to 9 ft) annual water-level changes, the well shows a trend toward generally increasing water levels in recent years. Water levels in this well may be impacted by pumping from other deep wells on Hilton Head Island.

Long-term water-level trends in the Gramling and Charleston aquifers

Long-term records for both HOR-0973 (Fig. 8) and MRN-0078 (Fig. 9) show a steady water-level decline in the Gramling aquifer in eastern South Carolina. In the past 20 years, the water level has dropped about 10 ft in eastern Horry County and about 20 ft in southern Marion County.

In Allendale County, water levels in the Gramling confining unit also have been dropping steadily during the past two decades; although here, the net decline since 1996 has only been about 3 ft (Fig. 10).

In Jasper County, the Charleston aquifer steadily dropped more than 15 ft between 2001 and 2013 (Fig. 11); and although the water level has continued to decline since 2013, the rate of decline has been slower, dropping about 4 ft in 5 years.

Water levels in the Hilton Head Island well BFT-2055 dropped 20 ft in the five years from 2000 to 2005; but then only another 5 ft during the next five years. Water levels have been stable or even recovered slightly from 2013 through 2018 (Fig. 12).

McQueen Branch Aquifer

Recent water-level trends in the McQueen Branch aquifer

During some or all of the eight years from 2011 through 2018, water levels were measured in 43 wells completed in the McQueen Branch aquifer (Fig. 13 and Appendix D). While no one water-level trend appeared consistently throughout the aquifer, this eight-year period saw record-low water levels measured in most wells. Water levels in some wells were strongly influenced by the 2011–2012 drought, while others showed little or no indication of that event. In many wells, water levels generally declined; but in a few wells, water levels consistently increased, and in others still, there was little overall change from 2011 to 2018. Some wells showed significant summer drawdowns followed by winter recoveries; other wells showed little to no seasonal pattern.

Of the 43 McQueen Branch monitoring wells included in this report, only 27 were monitored prior to 2011. Of those 27 wells, 22 had all-time lowest water levels during 2011–2018 (Table 7), and 4 had record-high water levels during 2011–2018 (Table 8).

In the eastern Coastal Plain, the one McQueen Branch monitoring well in Horry County (HOR-1326) shows recurring summer drawdowns of as much as 18 ft, with comparable recoveries beginning in late fall and continuing through the spring. The three years of data available from this well are insufficient to establish any general downward water-level trend.

In the Dillon County well DIL-0121 at Little Pee Dee State Park, the water level was very stable from 2011 into 2015, with seasonal water-level variations of only about 1 ft. Beginning in late 2015, the water level began a steady decline of as much as 1 ft per year, seemingly because there was very little recovery during the winter and spring months of those years. Large precipitation events associated with tropical storms in late 2016 and 2018 resulted in rapid but temporary water-level rises of 2 to 4 ft.

In the Darlington County well DAR-0228, the impact of the 2011–2012 drought is expressed primarily by relatively low water levels in the early months of those years. Annual maximum water levels beginning in 2013 are 2 to 3 ft higher than in 2011 and 2012; but after the drought, the magnitude of the summer drawdowns increased to 3 to 4 ft, resulting in water levels in 2015 and 2018 lower than any seen since the 2002 drought.

ft bls: feet below land surface

In northern Florence County, the water level in FLO-0128 showed a fairly steady rise, recovering about 10 ft from 2011 through 2018. In this area, water levels in the McQueen Branch aquifer continue to recover after the City of Florence reduced its groundwater usage in the late 1990s. In southern Florence County at Lake City, well FLO-0274 shows the opposite behavior. There, the water level steadily declined throughout the eight years, dropping more than 1 ft per year with almost no seasonal variation.

In southern Williamsburg County, the water level in WIL-0355 also shows a steady decline of about 1 ft per year, seemingly the result of a lack of winter recharge in most years.

In Lee County, annual high water levels in the McQueen Branch aquifer at Lee State Park (wells LEE-0075 and LEE-0179) were very consistent in the early months of each year from 2011 through 2018; but the magnitude and duration of summer drawdowns is greater in recent years, likely the result of increased groundwater withdrawals for agricultural irrigation. In well LEE-0075, new record low water levels were reached in 2011, 2012, 2015, and 2018.

Both McQueen Branch monitoring wells in Sumter County having data since 2011 (SUM-0488 and SUM-0492) show an overall lowering of the water level by 8 to 10 ft from 2011 through 2018, with a higher rate of decrease beginning in 2014. Two other wells (SUM-0146 and SUM-0153) having water-level data beginning in 2015 also show a general decline through 2018. All Sumter County wells show large seasonal variations, with summer drawdowns often more than 10 ft and sometimes as much as 30 ft.

Water levels in Richland County show seasonal variability, with typical yearly water-level ranges of less than 5 ft. The 2011–2012 drought resulted in water levels 2 to 3 ft lower than normal, but the effect of the drought was no longer apparent by the end of 2013. Water levels in two wells, RIC-0543 and RIC-0775, which have very similar behaviors, dropped significantly during the summer of 2015, but the water level in RIC-0585 did not.

Because the well LEX-0844 in southern Lexington County is located near the updip limit of the McQueen Branch aquifer and away from any major pumping, water levels in this well are primarily influenced by climatic variations. The effect of the 2011–2012 drought is seen as a steady water-level decline that continued into late 2013 and contributed to a record low water level set in August 2014. Water levels began recovering in late 2015 and rose steadily into 2018.

In central Orangeburg County, ORG-0079 shows the water level in the aquifer was fairly stable from 2011 into early 2014; but since 2014, greater summer drawdowns led to water-level declines of about 2 ft per year.

The water level in the McQueen Branch aquifer in Aiken County was generally stable from 2011 through 2018. Wells in the eastern part of the county (AIK-0826 and AIK-0845) show noticeably larger (8 to 10 ft) summer drawdowns since 2016, probably the result of recent increases in agricultural withdrawals, although each year the water levels recover fully, and no net decline in annual high water levels is observed. In western Aiken County (see AIK-0817 and AIK-2380), the aquifer seems less affected by agricultural pumping, with seasonal fluctuations of 2 ft or less.

In northern Barnwell County in the Town of Williston, well BRN-0078 has been measured since 2014. Here, water levels typically drop about 5 ft in the summer, but recover completely by early spring. A few miles to the south, wells BRN-0358 and BRN-0366 show a similar behavior; and in those wells, the 2011–2012 drought reduced the winter and spring water-level recovery in those years. Those two wells appear to show a modest decline in water levels during the eight years from 2011 through 2018; but because these wells are only measured about 4 times per year, the true annual highs and lows are uncertain. In southern Barnwell County, in wells BRN-0349 and BRN-0356, recurring seasonal drawdowns of about 2 ft have led to an overall decline in water level of about 3 ft from 2011 through 2018.

Water levels in all Allendale County wells trended downward in recent years, as winter and spring recoveries were rarely sufficient to raise water levels to the previous year's highest water level. In the northern part of the county, annual highest water levels in ALL-0358 gradually dropped about 3 feet during the eight years; and in central Allendale County, annual highest water levels in ALL-0377 dropped about 4 feet. ALL-0378, a flowing well located close to the Savannah River, had fairly consistent levels from year to year until 2014, when its water level dropped nearly 10 ft but only recovered about 4 ft.

Long-term water-level trends in the McQueen Branch aquifer

In eastern South Carolina in Dillon County, the water level in DIL-0121 steadily declined 11 ft in the five years from 2000 through 2004, then gradually recovered about 5 ft by 2010 (Fig. 14). Following four years of fairly stable conditions, water levels dropped about 2 ft from 2015 to 2018. In northern Darlington County, DAR-0228 has had fairly stable water levels since late 1999, with a range of water levels barely exceeding 6 ft (Fig. 15), although recent years have seen several short-term water-level changes of about 5 ft. In Lee County, McQueen Branch water levels in LEE-0075 have generally maintained a consistent level in the winter and early spring months during the past 20 years, but the magnitude of summer drawdowns has been increasing since 2011 (Fig. 16).

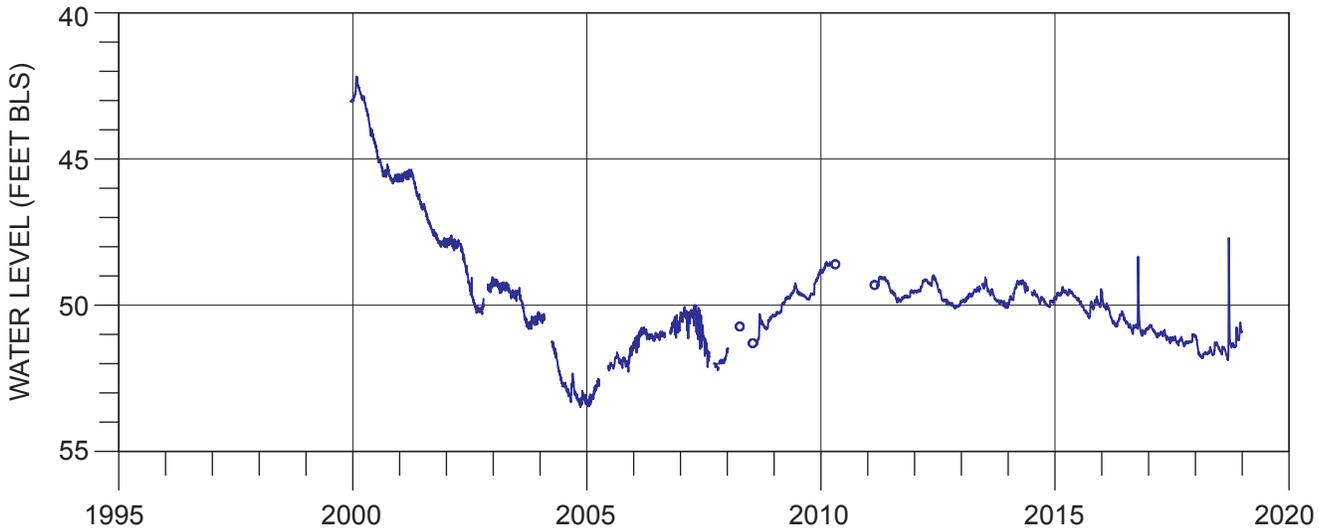

Figure 14. Period-of-record hydrograph for well DIL-0121 (McQueen Branch).

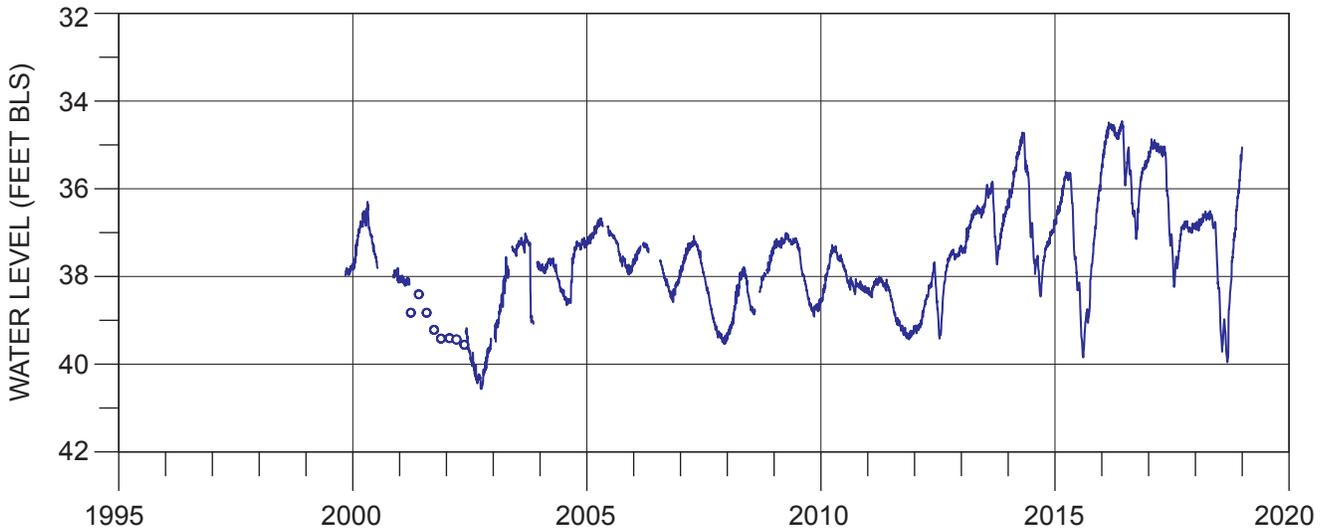

Figure 15. Period-of-record hydrograph for well DAR-0228 (McQueen Branch).

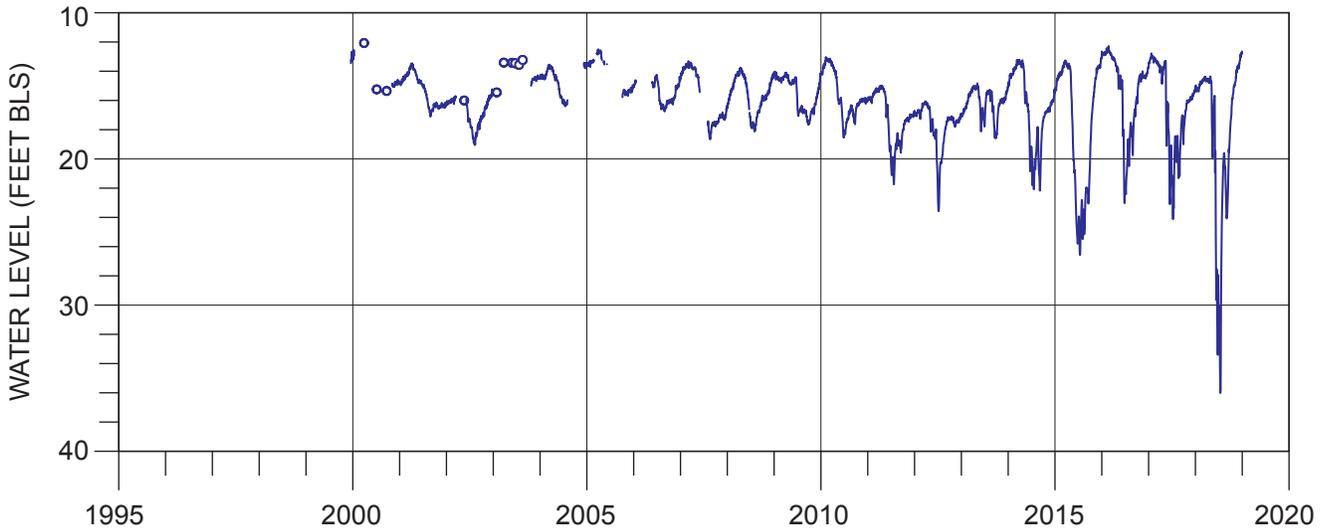

Figure 16. Period-of-record hydrograph for well LEE-0075 (McQueen Branch).

In northern Florence County, McQueen Branch water levels are still influenced by decades of pumping, particularly from wells operated by the City of Florence. In FLO-0128, the water level declined steadily throughout the 1980s and 1990s, until the City of Florence began to supplement its water supply with surface water from the Pee Dee River and reduced its groundwater pumping. After reaching an all-time low of 92.07 ft bls in August 1999, the water level generally has been recovering (Fig. 17). By the end of 2018, the water level reached 33.97 ft bls, although the rate of recovery has slowed since about 2010. In southern Florence County, however, the Lake City well FLO-0274 shows the water level in the

McQueen Branch aquifer continuing a generally steady decline of about one ft per year, dropping almost 9 ft from 2011 through 2018, and 20 ft from 2000 through 2018 (Fig. 18).

In Richland County, water levels have been fairly stable since the late 1990s, with measured water levels varying less than 10 ft in wells RIC-0543 (Fig. 19) and RIC-0585 (Fig. 20). The magnitude of seasonal variations is typically only a few feet, and water-level declines caused by drought are also only a few feet.

In Lexington County, the water level in LEX-0844 declined about 10 ft during the 1998–2002 drought and another 2 ft during the 2007–2008 drought. By late 2010,

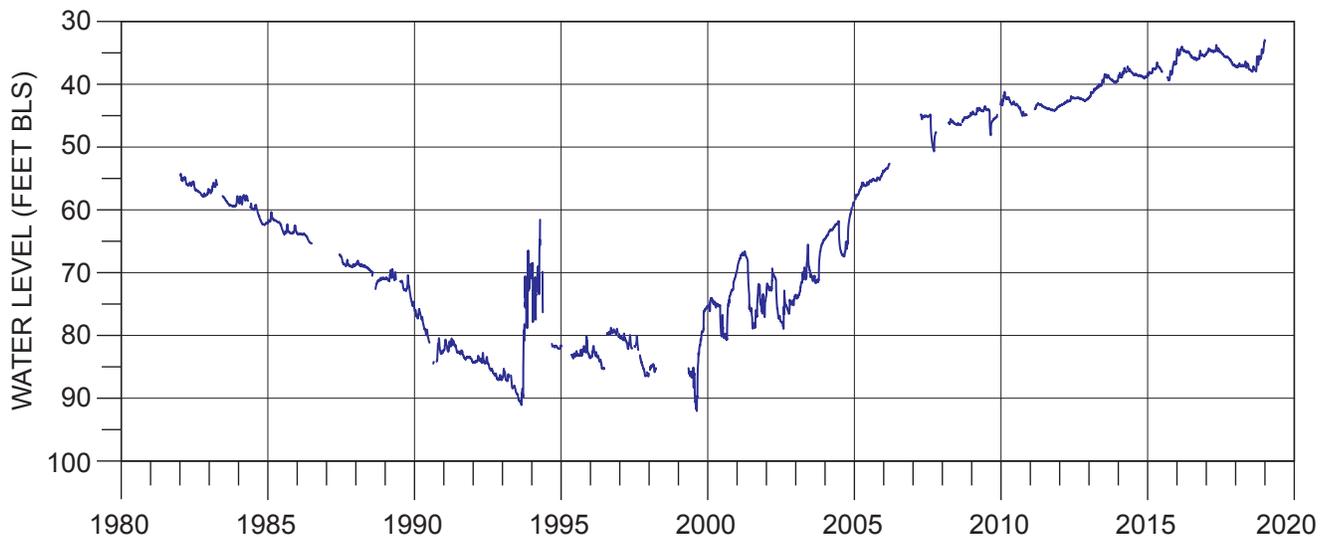

Figure 17. Period-of-record hydrograph for well FLO-0128 (McQueen Branch).

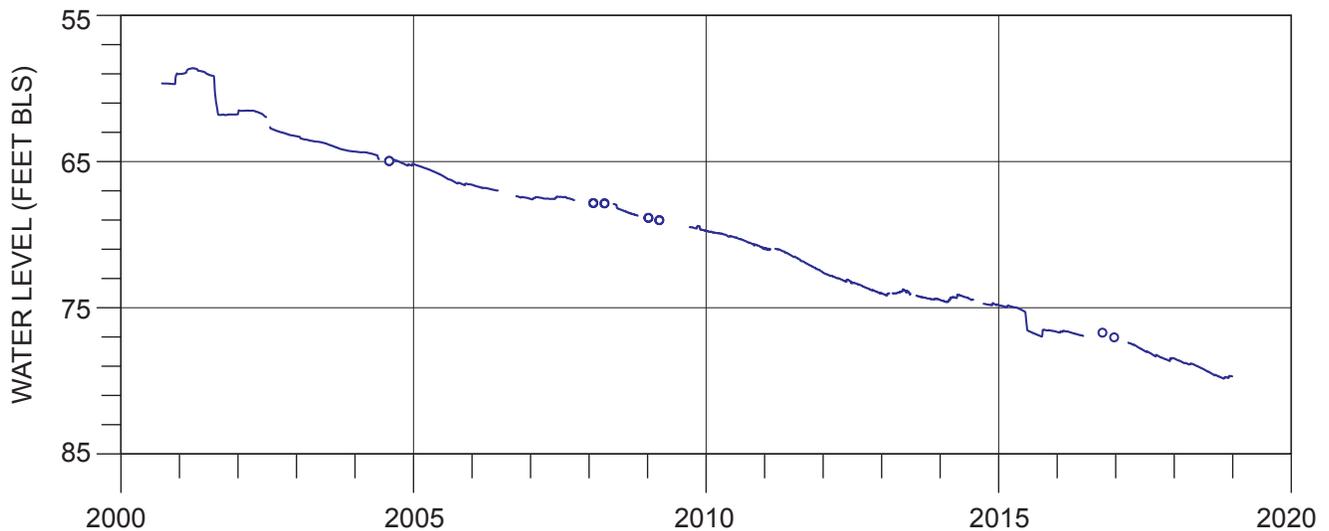

Figure 18. Period-of-record hydrograph for well FLO-0274 (McQueen Branch).

the water level recovered from the 2007–2008 drought, but steadily dropped another 3 ft by 2014. Heavy rains and generally wetter weather beginning in October 2015 reversed the downward trend, raising the water level about 6 ft from late 2015 through 2018, bringing the groundwater up to a level last seen in 2001 (Fig. 21).

In east-central Aiken County, water levels in AIK-0826 have been generally stable for more than a decade, although noticeably larger seasonal drawdowns have occurred each summer beginning in 2016 (Fig. 22), likely the result of increased agricultural withdrawals in recent

years. In western Aiken County, water levels in AIK-0817 declined about 3 ft from 2006 to 2013, then increased about 2 ft by the end of 2018 (Fig. 23). A similar trend is seen in AIK-2380 (Fig. 24). Throughout Aiken County, McQueen Branch water levels during the past decade remain about 5 ft lower than during the 1990s. Monitoring wells in Barnwell and Allendale Counties show a fairly steady water-level decline during the past decade, with water levels 10 to 15 ft lower than those seen in the mid-1990s (Figs. 25 and 26), and seasonal variations more pronounced in recent years.

Crouch Branch Aquifer

Recent water-level trends in the Crouch Branch aquifer

During some or all of the eight years from 2011 through 2018, water levels were measured in 41 wells completed in the Crouch Branch aquifer (Fig. 27 and Appendix E). While no one water-level trend appeared consistently throughout the aquifer, this eight-year period saw record low water levels in all but two wells. Water levels in some wells were strongly influenced by the 2011–2012 drought, while others showed little or no indication of that event. In many wells, water levels generally declined; but in a few wells, water levels consistently increased or showed little overall change from 2011 to 2018. Some wells showed significant summer drawdowns followed by winter recoveries while other wells showed little or no seasonal pattern.

Of the 41 Crouch Branch monitoring wells included in this report, 23 were monitored prior to the year 2011. Of those 23 wells, 21 had all-time low water levels during 2011–2018 (Table 9), and 2 had record-high water levels during those years (Table 10).

In eastern South Carolina, wells in Horry County show well-defined seasonal water-level fluctuations every year, with typical summer drawdowns in the range of 10 to 20 ft. Both Horry County wells (HOR-0290 and HOR-0309) with measurements throughout the 2011–2018 period show a steady water level decline totaling 10 to 20 ft during those eight years. In eastern Georgetown County, water levels in GEO-0382 and GEO-0383 steadily declined almost 8 ft from mid-2014 (when monitoring began) through 2017, with no significant seasonal variation.

At Little Pee Dee State Park in Dillon County, two Crouch Branch monitoring wells (DIL-0172 and DIL-0174) have been monitored since mid-2014. Both wells show only minor seasonal variation superimposed on a general decline of about 2 ft from early 2015 through the summer of 2018. In late 2016 and 2018, both wells showed water-level gains of 1.6 to 4.8 ft over the course of 3 to 4 days, followed by rapid drawdowns of a similar magnitude. The timing of those events corresponds to periods of heavy rain during tropical storms, but the mechanism causing this unusual water-level behavior is not well understood. Similar behavior during those storms is seen in other monitoring wells at Little Pee Dee State Park.

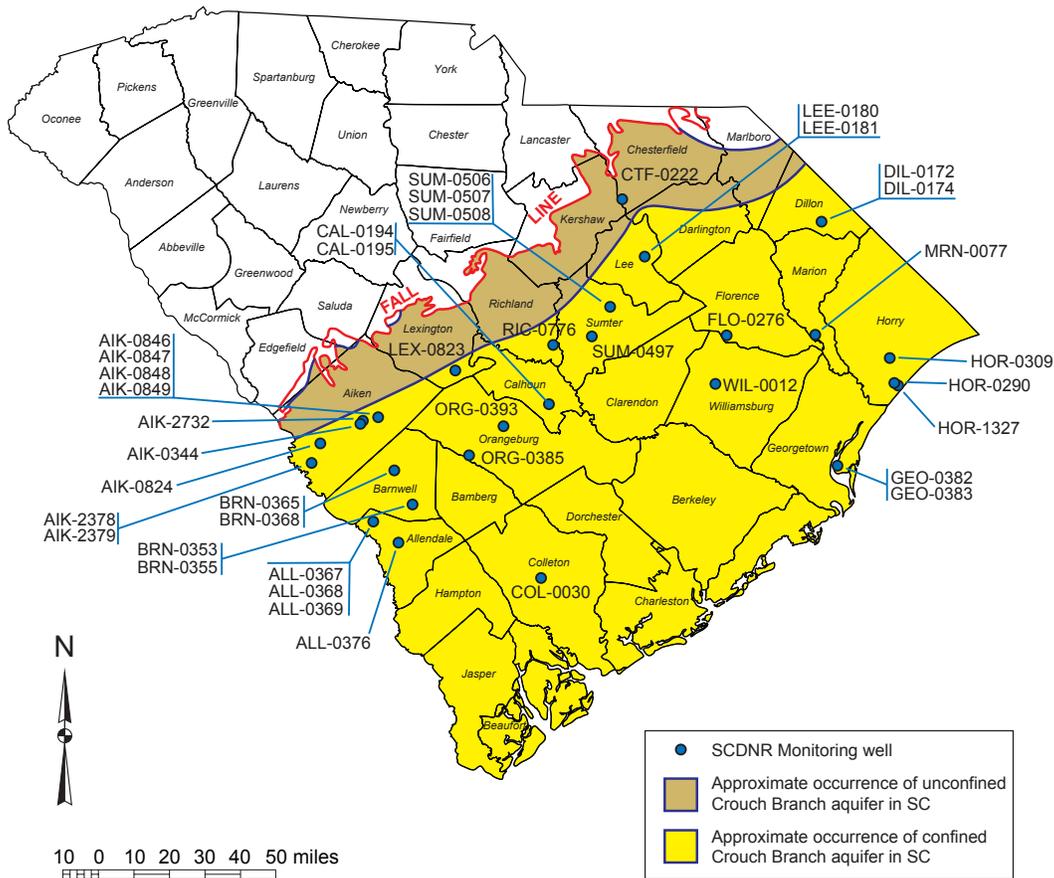

Figure 27. Map showing locations of Crouch Branch aquifer monitoring wells.

Table 9. Recent record-low water levels in the Crouch Branch aquifer

Well	Previous record low (Date)	New record low (Date)	Difference (ft)
AIK-0824	185.24 ft bls (11/17/2008)	186.21 ft bls (11/29/2013)	0.97

ft bls: *feet below land surface*

In southern Marion County, the water level in MRN-0077 steadily declined about 7 ft during the eight years from 2011 through 2018, and the one Crouch Branch well in Williamsburg County, WIL-0012 in Kingstree, has shown a fairly steady decline of about 5 ft from early 2016, when measurements began, through 2018.

In southern Florence County, FLO-0276 in Lake City shows water levels in the Crouch Branch aquifer declining almost 17 ft from early 2011 to late 2018. A short-lived 10-ft drawdown in late June 2016 is probably an effect of local pumping and not indicative of regional conditions in the aquifer at that time.

Both Crouch Branch monitoring wells in Lee County (LEE-0180 and LEE-0181) are located in Lee State Park and have been monitored since July 2012. Although screened in different zones within the aquifer, both wells show very similar water-level behaviors. Seasonal declines of 4 to 7 ft begin in the spring months and continue through the fall, but winter and early spring recoveries usually restore water levels to the high levels of the previous year.

Near McBee in southern Chesterfield County, CTF-0222 shows little or no seasonal water-level variation and responds slowly and slightly to larger-scale weather patterns. Small variations in daily average water level give the CTF-0222 hydrograph a noisy appearance. The variations are likely caused by nearby pumping.

Of the four Crouch Branch monitoring wells in Sumter County, three (SUM-0506, SUM-0507, and SUM-0508) are located at the same site, about 4 miles north of the City of Sumter, and have only been monitored since early 2017. In these wells, seasonal variations of up to 7 ft have occurred, but the limited amount of data precludes the identification of any general water-level trend. Southwest of the City of Sumter, at Manchester State Forest, water levels in the relatively shallow well SUM-0497 show little seasonal variation; but water levels vary in response to significant or long-term weather events, such as the 2011–2012 drought and the heavy rainfall of October 2015.

In southeastern Richland County, water-level data collected since 2015 in RIC-0776 show seasonal variations of 6 to 8 ft, with no apparent longer-term trend in the water level. Pumping of groundwater at the Dominion Energy Wateree Station power plant, and this well's shallow depth and proximity to the Wateree River, may account for the many rapid, short-term fluctuations seen on the hydrograph, as the aquifer here might have some connection to the nearby surface water system.

The one Crouch Branch well in Lexington County, LEX-0823, is located in the Town of Swansea. In this well, water levels were relatively low from late 2013, when monitoring began, through late 2015, after which water levels rose steadily until mid-2018. The water-level behavior in this well is almost identical to that of the nearby McQueen Branch well LEX-0844. The water-level elevations in each well are nearly identical, suggesting those aquifers are hydraulically connected in this area.

The two Crouch Branch monitoring wells in Calhoun County, CAL-0194 and CAL-0195, are both located at the SCDNR cluster site in the Town of Creston and are screened in different zones of the aquifer. Although water-level data collection only began in late 2013, the data show this aquifer is strongly impacted by groundwater pumping for agricultural irrigation in this area. The hydrographs of both wells are almost identical and are characterized by seasonal drawdowns of 40 to 50 or more ft each year. The water-level recovery that begins in September and continues into April brings the water level up to near the high of the previous year, but the few years of data collected so far suggest an overall lowering of water levels by almost 1 ft per year.

Water levels in the Crouch Branch aquifer in Orangeburg County also are strongly impacted by groundwater withdrawals for agricultural irrigation. ORG-0393, located in the City of Orangeburg in central Orangeburg County, shows large water-level declines occurring in May through August of most years, followed by water-level gains from September through March. No trend is seen in terms of the yearly high-water levels, but the magnitude of the summer drawdowns has increased since 2015. ORG-0385, a monitoring well at the Dominion Energy power plant near Cope in western Orangeburg County, also shows large summer drawdowns and comparable winter recoveries, but water levels in this well also are impacted by groundwater pumping by the power station, making for a much noisier hydrograph.

In eastern Aiken County, at the SCDNR cluster site C-3 at Aiken State Park, four wells monitor different zones in the Crouch Branch aquifer. The three deeper zones are monitored by AIK-0846, AIK-0847, and AIK-0848, while AIK-0849 monitors the shallower zone. The three deeper wells exhibit similar behaviors, and show the magnitude of summer drawdowns becoming noticeably greater beginning in 2015, with declines of about 10 ft occurring in 2016 and 2018. While this trend is similar to those seen in Orangeburg and Calhoun Counties, here, the annual springtime highest water level increases slightly each year from 2012 through 2018. The shallower zone also shows seasonal variations, but such variations range only about 2 ft or less, even in recent years. Four to five mile west of the C-3 site, two monitoring wells (AIK-0344 and AIK-2732) show water-level behaviors similar to that seen in AIK-0847, except in these two wells, seasonal water-level drawdowns measured since 2016 have magnitudes of 20 to 40 ft.

In western Aiken County at the SCDNR cluster site C-2, the well AIK-0824 responds slowly to long-term wet or dry periods and shows almost no seasonal water-level variations, and the range of water levels was just over 2 ft from 2011 through 2018. At this site, the Crouch Branch aquifer water levels are very similar to those seen in the McQueen Branch aquifer (well AIK-0817). In southwestern Aiken County, at the SCDNR cluster site C-1, water

levels in AIK-2378 and AIK-2379 show small seasonal variations of less than 2 ft per year and generally stable water levels between 2011 and 2018.

In central Barnwell County at the SCDNR cluster site C-5, the two wells screened in different zones of the Crouch Branch aquifer (BRN-0365 and BRN-0368) show very similar water-level patterns. Here, annual water-level variations have increased notably since 2014, with seasonal drawdowns of up 8 ft; but winter recoveries reach about the same depth each year, resulting in no apparent overall water-level decline since 2011. The SCDNR cluster site C-6, located in southeastern Barnwell County, also has two wells screened in different zones of the Crouch Branch aquifer (BRN-0353 and BRN-0355). The hydrographs of the two C-6 wells look very similar to those at C-5, except the seasonal water-level declines are slightly greater and the winter recoveries do not return water levels to those of the previous year, resulting in a decline of 1 ft per year since 2014.

Three of the four SCDNR Crouch Branch monitoring wells in Allendale County (ALL-0367, ALL-0368, and ALL-0369) are located at the C-7 cluster site in the northwestern part of the county. The fourth Allendale County well (ALL-0376) is located at the C-10 cluster site in the central part of the county. Seasonal water-level fluctuations are prominent on all the hydrographs, with annual changes of 4 to 8 ft typical. Peak annual water levels have declined steadily since 2014, lowering about 3 ft at C-7 and 4 ft at C-10 in that 4-year period.

The well COL-0030, located in Walterboro in Colleton County, is the southernmost and deepest Crouch Branch well in the SCDNR network. In recent years, summer drawdowns have been about 1 ft or less, while winter recoveries have been about 2 ft, resulting in a consistent water-level increase of almost 8 feet since 2013.

Long-term water-level trends in the Crouch Branch aquifer

In eastern South Carolina, water levels in the Crouch Branch aquifer have been in a long-term, steady decline. In Horry County, the water level in the Myrtle Beach well HOR-0290, which had recovered more than 100 ft between 1988 and the early 2000s, dropped about 20 ft in the past 10 years (Fig. 28). In Conway, the water level in HOR-0309 was generally stable from 2001 to 2006; but from late 2006 to 2018, water levels dropped more than 30 ft (Fig. 29). The water level in well MRN-0077, in southern Marion County, continued a steady decline of about 1 ft per year since measurements began in 1983 (Fig. 30). The water level in well FLO-0276, in southern Florence County, has also dropped more than 25 ft since 2001 (Fig. 31).

In Orangeburg County, the aquifer has seen smaller declines than in the east. In ORG-0393, annual high water levels have declined less than 10 ft since 2001, but seasonal drawdowns have become much larger in recent years (Fig. 32).

In western South Carolina in Aiken County, the aquifer had relatively high, stable water levels throughout most of the 1990s, followed by about 10 years of declining water levels beginning around 1998, during which water levels declined 5 to 10 ft, after which water levels have been generally stable (Figs. 33–35). Similar trends are seen in Barnwell and Allendale Counties, except in recent years the water levels show more decline (Figs. 36 and 37).

The water level in central Colleton County in COL-0030 has steadily recovered 10 ft since late 2008, before which it was declining at about 2 ft per year since 2004 (Fig. 38). By the end of 2018, the water level had recovered almost to a level last seen in 1998.

Gordon Aquifer

Recent water-level trends in the Gordon aquifer

During some or all of the eight years from 2011 through 2018, water levels were measured in 21 wells completed in the Gordon aquifer (Fig. 39 and Appendix F). No one water-level trend appeared consistently throughout the aquifer. Some wells showed a slight downward trend, but other wells seemed to increase whereas others still showed little net change. Most wells having data throughout the eight years showed lower water levels during the 2011–2012 drought, but a few wells seemed unaffected by that event.

Of the 21 Gordon monitoring wells included in this report, 15 were monitored prior to the year 2011. Of those 15 wells, 11 had all-time low water levels during 2011–2018 (Table 11), and 5 had record-high water levels during those years (Table 12).

In Barnwell County, water levels in wells at the two monitoring sites C-5 and C-6 behave similarly, with lowest water levels occurring in 2011 and 2012 and well-defined seasonal fluctuations in subsequent years. Wells at C-5 (BRN-0359 and BRN-0367) show noticeably greater seasonal variation than do wells to the south at the C-6 site (BRN-0352 and BRN-0354). In Allendale County, water levels in wells at both monitoring sites C-7 and

C-10 behave much like the C-5 site in Barnwell County; but at the C-7 site (wells ALL-0365 and ALL-0366) annual water-level changes of 10 to 16 ft are typical, about twice that seen at C-10 and C-5. After the 2011–2012 drought, no general trend is seen in Gordon aquifer water levels in this area.

In central Orangeburg County, the water level in ORG-0430 reached a new record low in September 2011; but by April 2014 water levels had recovered to levels not seen in the prior 10 years. Seasonal water-level fluctuations typically are 6 to 10 ft, but a 15-ft decline during the summer of 2015 led to a new record low water level in September. Water levels have been fairly stable since 2016. In southern Calhoun County, the water level in well CAL-0193 behaves very much like that of ORG-0430, except the magnitude of annual variations in Calhoun County is about half that seen in Orangeburg County.

HAM-0050, in southern Hampton County, shows little annual water-level fluctuation. After recovering from the 2011–2012 drought, water levels have been very stable since mid-2014.

In BRK-0644, water levels were low during the 2011–2012 drought but recovered to normal levels by early 2013. Although relatively large summer declines of 6 to 9 ft occurred in 2013 through 2016, winter recoveries of the same magnitude kept the water level generally stable from 2013 through 2018.

ft bls: *feet below land surface*

The five years of data available from the coastal well CHN-0990 show the lowest water levels occurring in the late summer of 2014 and 2015, followed by three years of very stable water levels during 2016 through 2018. Although missing data for most of the 2011–2012 drought, water levels in CHN-0101 appear to be relatively low during those years, but recover to normal levels in 2013, with little variation through 2018.

Water levels in CHN-0803, located near the South Santee River, vary from day to day, but generally stay within a range from 8 to 9 ft. At this site, the aquifer is probably unconfined and may have a hydraulic connection to the South Santee River. High water levels observed in late 2015, 2016, and 2017 are likely the result of large rainfall events associated with tropical storms. Water levels measured since late 2016 in GEO-0387, in southern Georgetown County, suggest the Gordon aquifer north of the Santee River behaves very much the same as the aquifer does in CHN-0803.

The water level in CHN-0044, located at the western edge of the City of Charleston, recovered about 10 ft from late 2012 to early 2016 and was about 3 ft higher at the end of 2018 than at the beginning of 2011. Water levels measured in CHN-0989 since mid-2014 show annual fluctuations of up to 6 ft, with both drawdowns and recoveries decreasing each year through 2018, resulting in a water-level decline of almost 1 ft per year. In southwestern Charleston County at Edisto Island, the water level in CHN-0484 dropped about 6 ft from early 2011 to late 2013, but only recovered 4 ft by 2016. New record lows were set in 2012, 2013, 2014, 2016, and 2018.

In the southernmost Gordon monitoring well, COL-0301 at Edisto Beach, water levels typically fluctuate 6 to 8 ft per year; and water levels have been generally stable from 2013 through 2018, although a new record low water levels were reached in 2013, 2014, and 2018.

Long-term water-level trends in the Gordon aquifer

The long-term water-level trend in the Gordon aquifer in Allendale and Barnwell Counties is typified by that of ALL-0375 (Fig. 40). Water levels were relatively high throughout most of the 1990s, then lowered about 10 ft during the 1998–2002 drought, and again another 5 ft during the 2007–2008 drought. Some recovery began in 2013; and water levels have been generally stable since 2014, although the magnitude of summer drawdowns has increased in recent years.

In central Orangeburg County, ORG-0430 shows a steady water-level decline of almost 1 ft per year since 2004, only occasionally interrupted by water-level increases during wet years, such as 2013 (Fig. 41). Water levels in recent years are similar to those seen during the drought in 2002.

In Hampton County, HAM-0050 shows generally steady water levels since 2001, except for water-level declines that occurred during extended periods of dry weather in 2001–2002 and 2007–2012 (Fig. 42).

Closer to the coast, two general patterns appear in the long-term hydrographs. In wells north of the City of Charleston (BRK-0644, CHN-0101, and CHN-0803), where the aquifer is fairly shallow and poorly confined or unconfined, long-term water levels have been generally stable (Figs. 43–45). In northeastern Charleston County and southern Georgetown County, the aquifer may have some hydraulic connection to the Santee River, which would help maintain water levels in the aquifer. South of the City of Charleston, where the aquifer is deeper, water levels have been declining during the last 20 years or more. In CHN-0044, the water level dropped almost 30 ft from 1983 to 2012 (Fig. 46); and in both CHN-0484 and COL-0301, the water levels steadily dropped 20 ft from 2000 to 2018 (Figs. 47 and 48).

Upper Floridan and Middle Floridan Aquifers

Presenting wells from the Upper Floridan and Middle Floridan aquifers together in this report is not unreasonable. In some updip areas, such as Aiken and Barnwell Counties, the confining unit above the Middle Floridan aquifer can be discontinuous and somewhat ineffective; and in downdip areas, such as Beaufort County, little difference is seen in the water levels of the Upper Floridan and Middle Floridan aquifers.

Recent water-level trends in the Upper and Middle Floridan aquifers

During some or all of the eight years from 2011 through 2018, water levels were measured in 32 wells completed in the Upper Floridan or Middle Floridan aquifers (Fig. 49 and Appendix G), and no one water-level trend was observed throughout all wells. In Beaufort County, water levels in both the Upper Floridan and Middle Floridan aquifers were stable during this eight-year

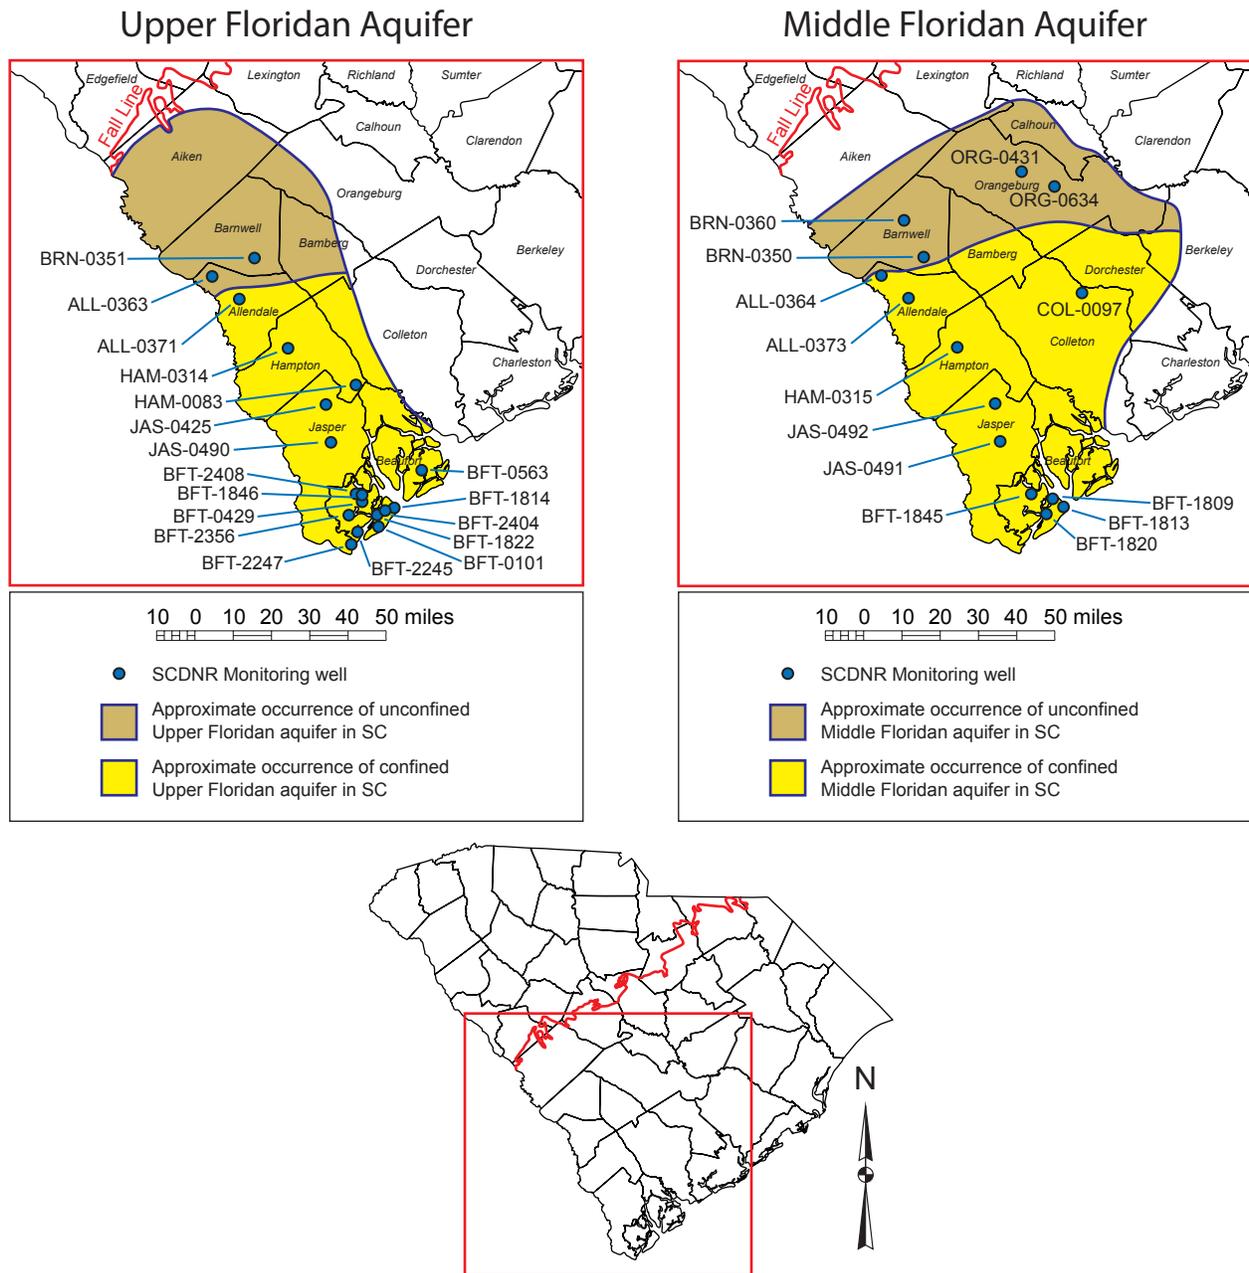

Figure 49. Map showing locations of Upper Floridan and Middle Floridan aquifer monitoring wells.

period, with very little difference in water levels from one year to another. In most wells outside of Beaufort County, the hydrographs are defined by relatively low water levels during the 2011–2012 drought and generally stable water levels after some degree of recovery from that drought.

Of the 32 Upper or Middle Floridan monitoring wells included in this report, 22 were monitored prior to the year 2011. Of those 22 wells, 16 had all-time low water levels during 2011–2018 (Table 13), and 9 had record-high water levels during those years (Table 14).

In northern Barnwell County, the Middle Floridan well BRN-0360 at the C-5 monitoring site saw a water-level decline of about 3 ft during 2011 and 2012. From its lowest level in early 2013, the water level rose about 12 ft during the next 4 years, a recovery interrupted by summer declines of up to 4 ft. In southern Barnwell County, the Upper Floridan (BRN-0351) and Middle Floridan (BRN-0350) wells at the C-6 site have very similar hydrographs and water-level elevations. In both wells, a steady drawdown of almost 4 ft in 2011 and 2012 led to record low water levels in early 2013, followed by a fairly steady rise of about 10 ft by early 2017.

In Allendale County, both the Upper Floridan and Middle Floridan aquifers are monitored at two sites, C-7 in the northern part of the county (wells ALL-0363 and

ALL-0364) and C-10 in the central part of the county (wells ALL-0371 and ALL-0373). At C-7, both Upper and Middle Floridan aquifers respond slowly to long-term weather events and show no seasonal variation, and water-level elevations are very similar in both aquifers. In both wells, water levels were lowest in early 2013 and then rose slowly and steadily until mid-2016. At C-10, seasonal variations in the Upper Floridan are about twice as large as those in the Middle Floridan, and the water-level elevation in the Upper Floridan is about 35 ft higher than in the Middle Floridan. Unlike at C-7, water levels at C-10 fully recovered from the 2011–2012 drought by mid-2013.

The hydrograph of ORG-0431, a Middle Floridan well in the City of Orangeburg, shows the 2011–2012 drought lowered water levels in this area by 3 to 5 ft. After recovering by mid-2013, water levels were fairly stable into 2017, when water levels began dropping in response to dry weather in 2017 and 2018. In this well, water levels vary less than 6 ft during each year, and summer drawdowns are 4 ft or less. About 9 miles to the south-south-east is ORG-0634, another Middle Floridan well with a very different water-level pattern. Water levels in ORG-0634 are strongly impacted by pumping from nearby irrigation wells, especially since 2015, and are characterized

Table 13. Recent record-low water levels in the Upper Floridan and Middle Floridan aquifers

Well	Previous record low (Date)	New record low (Date)	Difference (ft)

ft bls: *feet below land surface*

by very large seasonal fluctuations, often 25 ft or more. The difference between highest and lowest recorded water levels is more than 60 ft, and water levels in 2015 and 2016 were at times more than 20 ft lower than at any time in 2011. Despite the magnitude of these summer drawdowns, water levels generally recover by early spring, and no obvious pattern of overall decline is apparent in this well.

The one Floridan aquifer monitoring well in Colleton County is COL-0097, a Middle Floridan well located along the northeastern edge of the county. After reaching a new record-low water level in late 2011, water levels rose quickly and steadily into early 2014, and continued rising at a lesser rate through 2018. Here, the aquifer shows little seasonal fluctuation.

In central Hampton County, HAM-0314 and HAM-0315 are Upper Floridan and Middle Floridan wells, respectively, located at Lake Warren State Park. Both wells show very similar water-level behaviors since monitoring began in early 2015. The hydrographs of both wells are defined by relatively large summer drawdowns in 2015 and 2016, and much smaller declines in 2017 and 2018. At this site, the Upper Floridan aquifer experiences slightly larger annual water-level variations than does the Middle Floridan.

At the southeastern edge of Hampton County in Yemassee, the Upper Floridan well HAM-0083 set a record-low water level in late 2011. By mid-2013, water levels recovered from the 2011–2012 drought and remained generally stable through 2018, varying only 4 ft or less each year.

In northern Jasper County, at the SCDNR cluster site C-15, monitoring wells in both the Upper Floridan (JAS-

0425) and Middle Floridan (JAS-0492) have nearly identical water levels throughout the 2011–2018 period. Water levels were relatively low from mid-2011 to early 2013, with the lowest levels occurring in September 2011. From 2013 through 2018, water levels were generally stable, with annual fluctuations of 10 ft or less. In southern Jasper County, wells in both the Upper Floridan (JAS-0491) and Middle Floridan (JAS-0490) also show nearly identical water levels since monitoring began in mid-2015, and the water levels here behave very much like that those at the C-15 site.

Throughout Beaufort County, both the Upper Floridan and Middle Floridan aquifers are characterized by recurring seasonal water-level fluctuations of 10 ft or less, with little net change in water level from year to year. In all 15 monitoring wells, annual high water levels are generally very consistent within each well, usually varying less than 2 ft from 2011 through 2018. In some wells, the annual high water level gradually declined about 1 ft by 2018; but in other wells, there was little net change from 2011. At the three sites at which wells monitor both the Upper Floridan and Middle Floridan, the hydrographs of both aquifers appear very similar, and the water-level elevations are nearly the same.

The three years of data available in BFT-0563 shows the Upper Floridan behaving somewhat differently on St Helena Island. Here, the water level reaches its annual high in the early fall, rather than in the late winter or spring, then steadily declines about 2 ft into late spring or summer, with annual lows occurring around June or July. This somewhat unusual timing of water-level fluctuations may be caused by different agricultural groundwater-use patterns in this area.

Long-term water-level trends in the Upper and Middle Floridan aquifers

The period-of-record hydrograph of BRN-0360 (Fig. 50) shows a pattern of water levels commonly seen in the Upper Floridan and Middle Floridan aquifer in Barnwell County since the late 1980s. Water levels are seen to be relatively high in the wet years of the mid-1990s and low during the droughts of 2007–2008 and 2011–2012. Since 2016, water levels have been similar to those seen during the mid-1990s. In this area, water levels appear to be controlled more by long-term weather patterns than groundwater withdrawals.

In northern Allendale County, at the C-7 site, the Middle Floridan well ALL-0364 saw its highest water level in 1998 and then dropped about 15 ft by 2002.

Because the aquifer here responds slowly to changing weather patterns, the water level did not recover much in 2003 and declined slowly for the next decade (Fig.51). After reaching a record low in early 2013, the water level steadily rose more than 10 ft by 2016, reaching high water levels not seen in 20 years. Located at the same site, the Upper Floridan well ALL-0363 has an almost identical water-level history as that of ALL-0364.

In central Allendale County, at the C-10 site, the Upper Floridan well ALL-0371 also saw its highest water level in 1998, which then dropped about 15 ft to a record low in 2002 (Fig.52). A partial recovery from the 2002 drought was followed by 10 years of fairly stable water levels, then another 5 ft recovery in 2013. Water levels in recent years are higher than any since 1998. Compared to the C-7 site, the Floridan aquifers at C-10 seem to show a

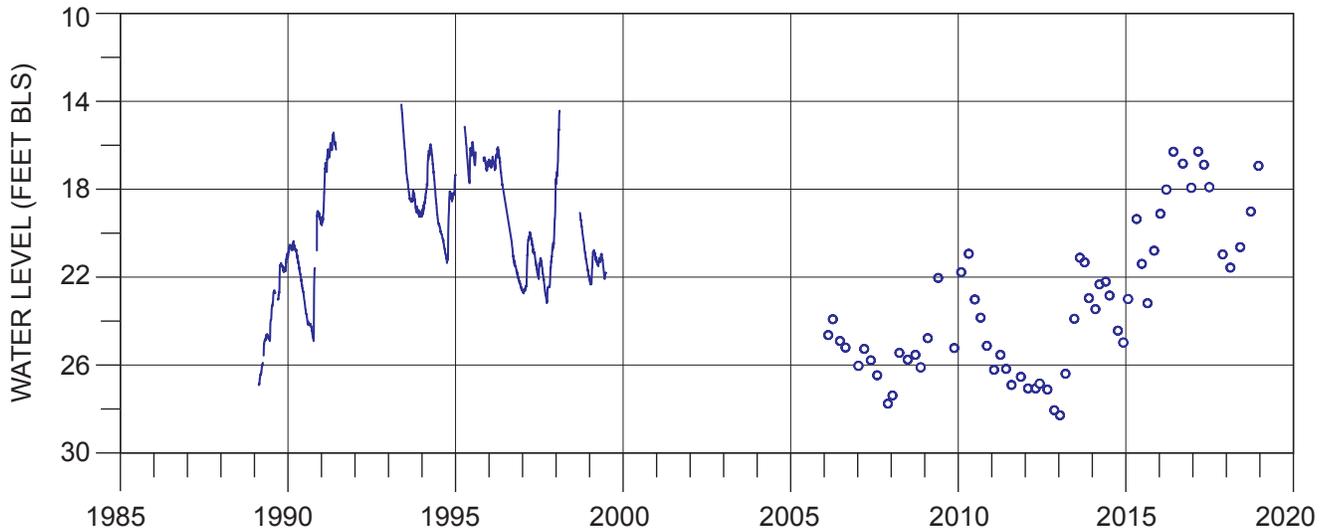

Figure 50. Period-of-record hydrograph for well BRN-0360 (Middle Floridan).

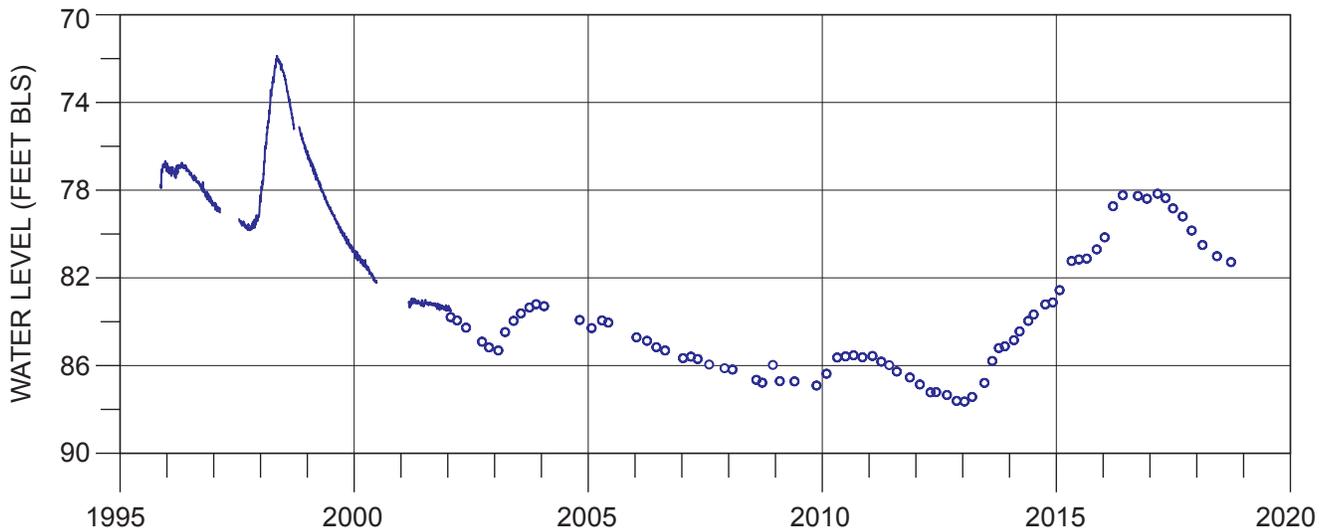

Figure 51. Period-of-record hydrograph for well ALL-0364 (Middle Floridan).

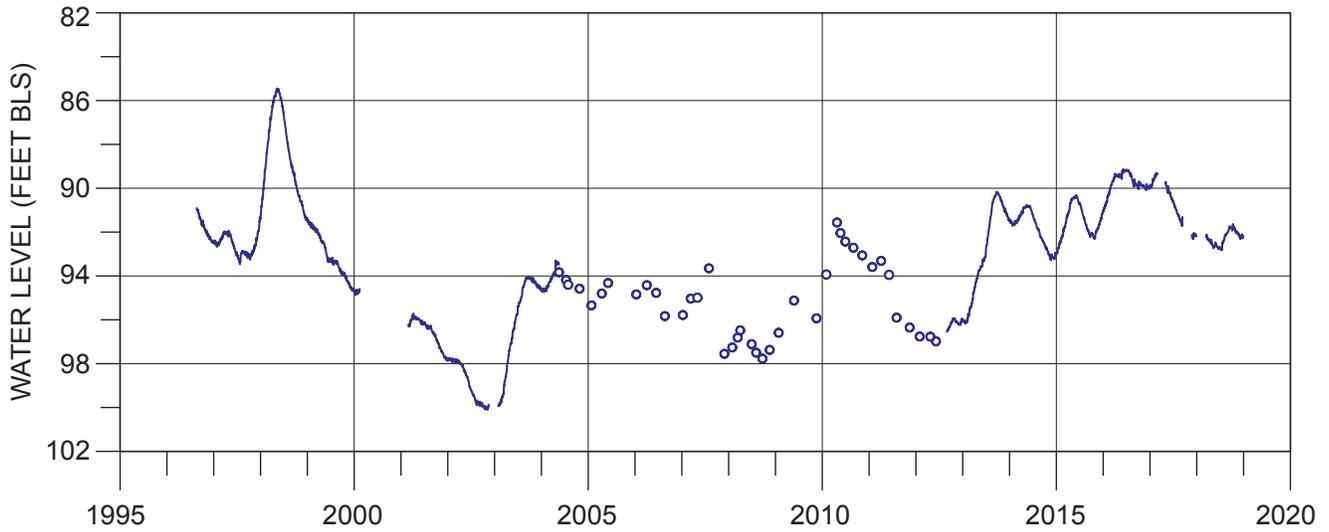

Figure 52. Period-of-record hydrograph for well ALL-0371 (Upper Floridan).

quicker response to changing weather conditions, allowing for a quicker recovery from drought and also greater seasonal water-level fluctuations.

The water level in the Middle Floridan well ORG-0431 was lowest in late 2002, but the water level recovered quickly the next year and remained generally stable for the next ten years. Since 2013, the water level in this well has been relatively high (Fig. 53).

The water level in the Middle Floridan well COL-0097 was in a near constant decline from 1977 through 2011, lowering by almost 24 ft during that time, but a recovery beginning in 2012 raised the water level 10 ft by 2018 (Fig. 54).

From the late 1970s to the late 1990s, the water level in the Upper Floridan well HAM-0083 in southeastern Hampton County was very stable and showed only small seasonal variations and little response to drought (Fig. 55). Since the late 1990s, the magnitude of seasonal variations has increased, resulting in lower annual minimum water levels and more pronounced water-level declines during periods of drought. A very similar pattern is seen in JAS-0425, a nearby Upper Floridan well monitored since the year 2000 (Fig. 56).

In Beaufort County, the Upper Floridan monitoring wells BFT-0101 and BFT-0429 have very long periods of record, and the hydrographs of those wells illustrate how

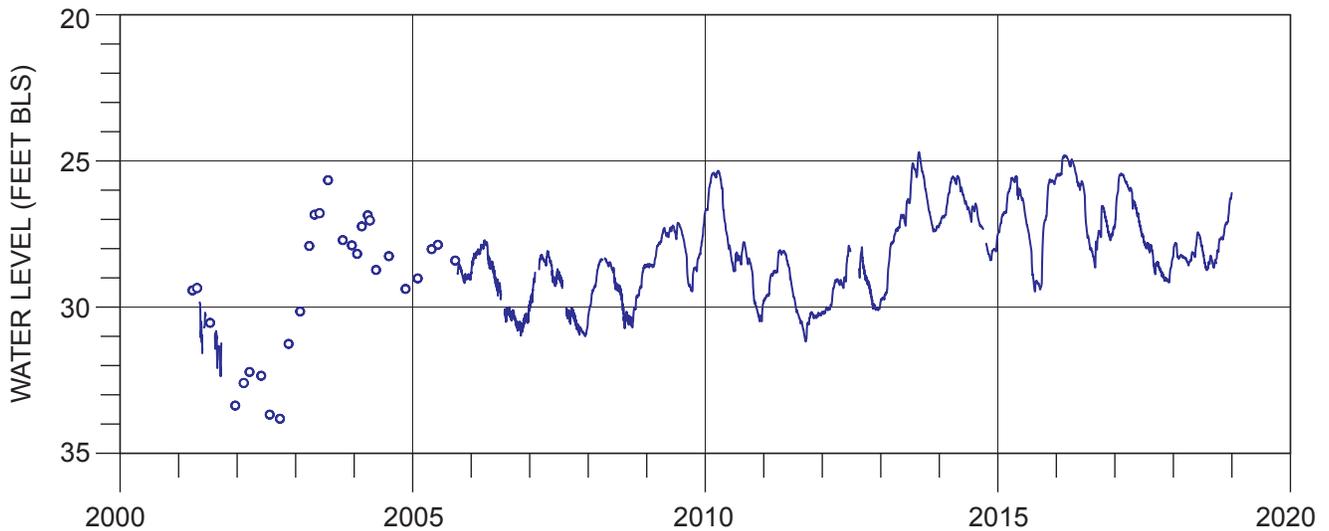

Figure 53. Period-of-record hydrograph for well ORG-0431 (Middle Floridan).

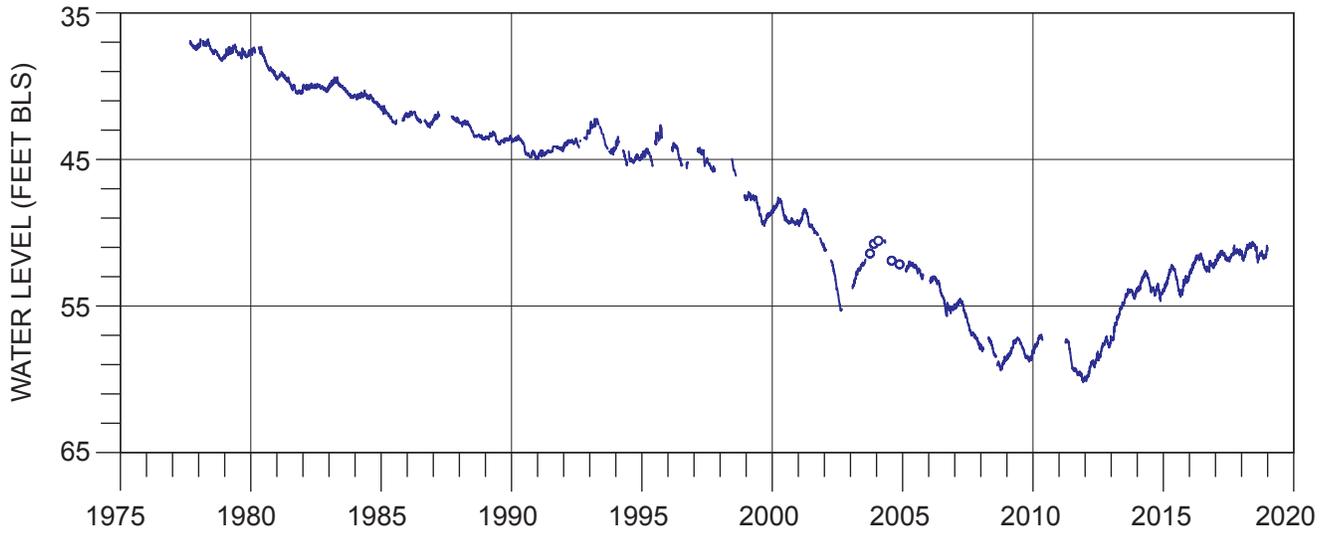

Figure 54. Period-of-record hydrograph for well COL-0097 (Middle Floridan).

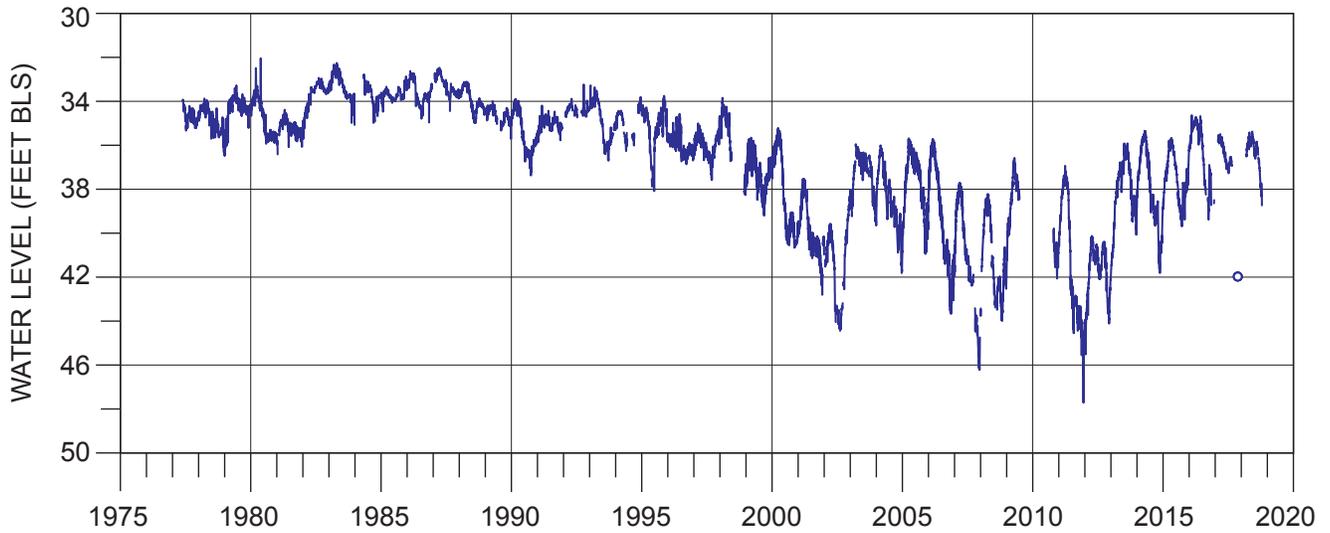

Figure 55. Period-of-record hydrograph for well HAM-0083 (Upper Floridan).

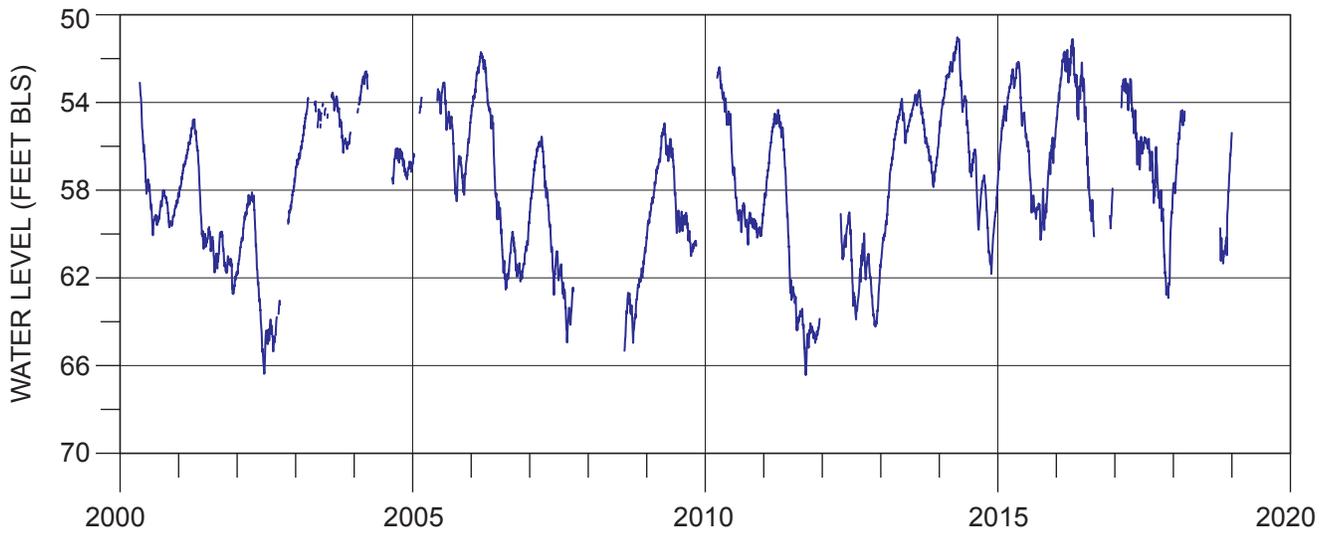

Figure 56. Period-of-record hydrograph for well JAS-0425 (Upper Floridan).

water levels have changed in the Hilton Head Island area during the past five decades (Figs. 57 and 58). Both wells show water levels declining during the 1970s and 1980s. Although the magnitude of decline is small—less than 10 ft—water levels in the aquifer were lowered below sea level, allowing for saltwater intrusion along the northern end of Hilton Head Island. Since about 1990, the decline stopped, but the magnitude of seasonal fluctuations increased, resulting in lower water levels during the summer months in recent years. This trend is most apparent in BFT-0429.

Other Beaufort County monitoring wells have water-level data going back as far as the mid-1980s, and

those wells show water-level patterns very similar to BFT-0101 and BFT-0429. Water levels in both the Middle Floridan well BFT-1845 (Fig. 59) and the Upper Floridan well BFT-1846 (Fig. 60) show an almost identical pattern to BFT-0429, which is located about one mile to the south. On northern Hilton Head Island, wells BFT-1809, BFT-1813, and BFT-1814 also have historical water-level patterns very similar to that of BFT-0429 (Figs. 61–63). Prior to 2010, the magnitude of seasonal fluctuations in both the Upper Floridan and Middle Floridan aquifers was about the same; but in recent years, the magnitude of seasonal fluctuations in the Middle Floridan aquifer has increased more than 50 percent.

APPENDIX A

Groundwater Levels in the Crystalline-Rock Aquifer 2011–2018

COUNTY: Anderson
 AQUIFER: Crystalline rock
 LOCATION: Williamston.

WELL NUMBER: AND-0326
 LATITUDE / LONGITUDE: 34.62267° / -82.48188°

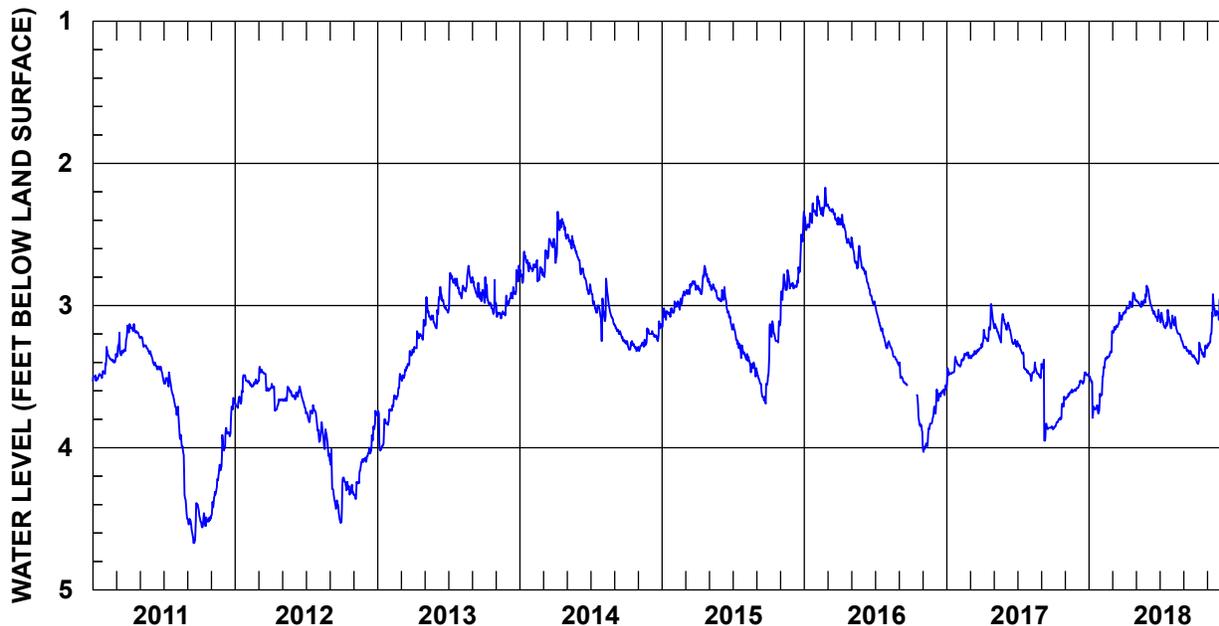

WELL CHARACTERISTICS: Observation well. Depth: 398 ft. Open hole below 75 ft.

LAND SURFACE ELEVATION: 788 ft.

PERIOD OF RECORD: October 1993 through 2018.

EXTREMES: High: 1.90 ft bls (April 23, 1998) Low: 5.64 ft bls (June 24, 2002).

REMARKS: Monitored by USGS until December 2009, then by SCDNR to September 2016, then by USGS.

COUNTY: Greenville

WELL NUMBER: GRV-2543

AQUIFER: Crystalline rock

LATITUDE / LONGITUDE: 35.12633° / -82.57135°

LOCATION: Marietta, 7 miles north-northwest (Jones Gap State Park).

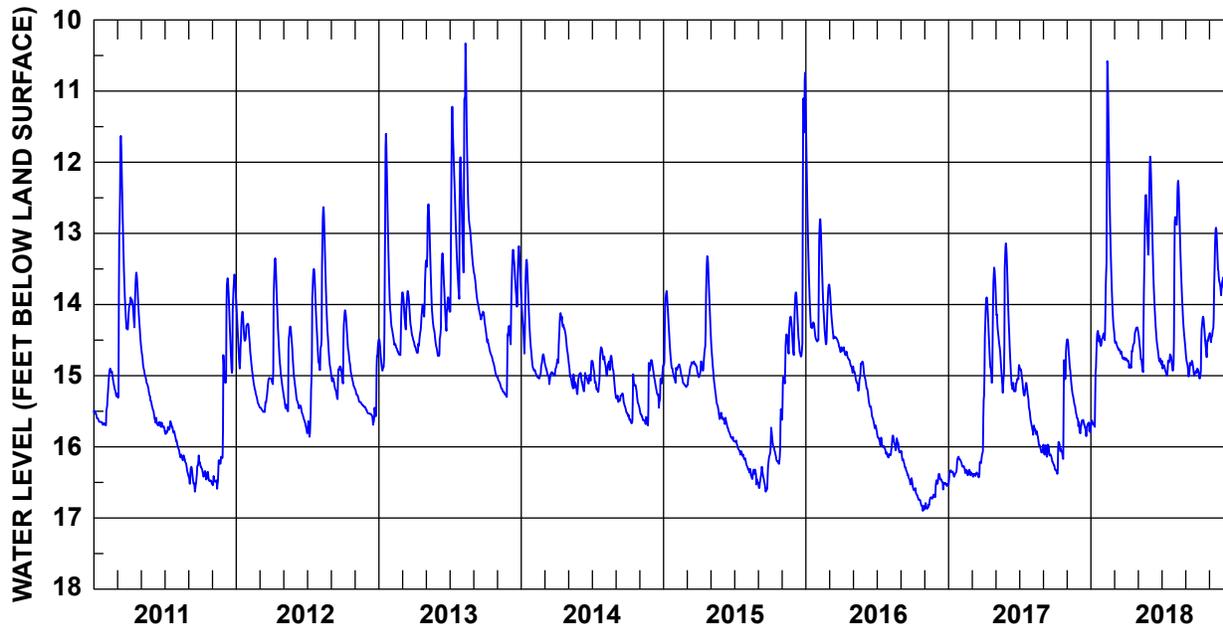

WELL CHARACTERISTICS: Unused fish hatchery well. Depth: 50 ft. Open interval unknown.

LAND SURFACE ELEVATION: 1,329 ft.

PERIOD OF RECORD: October 1997 through 2018.

EXTREMES: High: 10.33 ft bls (August 11, 2013) Low: 17.40 ft bls (October 3, 2007).

REMARKS: Shows minor pumping effects from nearby public supply well. May be open to saprolite.

COUNTY: Laurens

WELL NUMBER: LRN-1707

AQUIFER: Crystalline rock

LATITUDE / LONGITUDE: 34.38128° / -82.00628°

LOCATION: Mountville, 1 mile northwest (former Mountville Fire Tower).

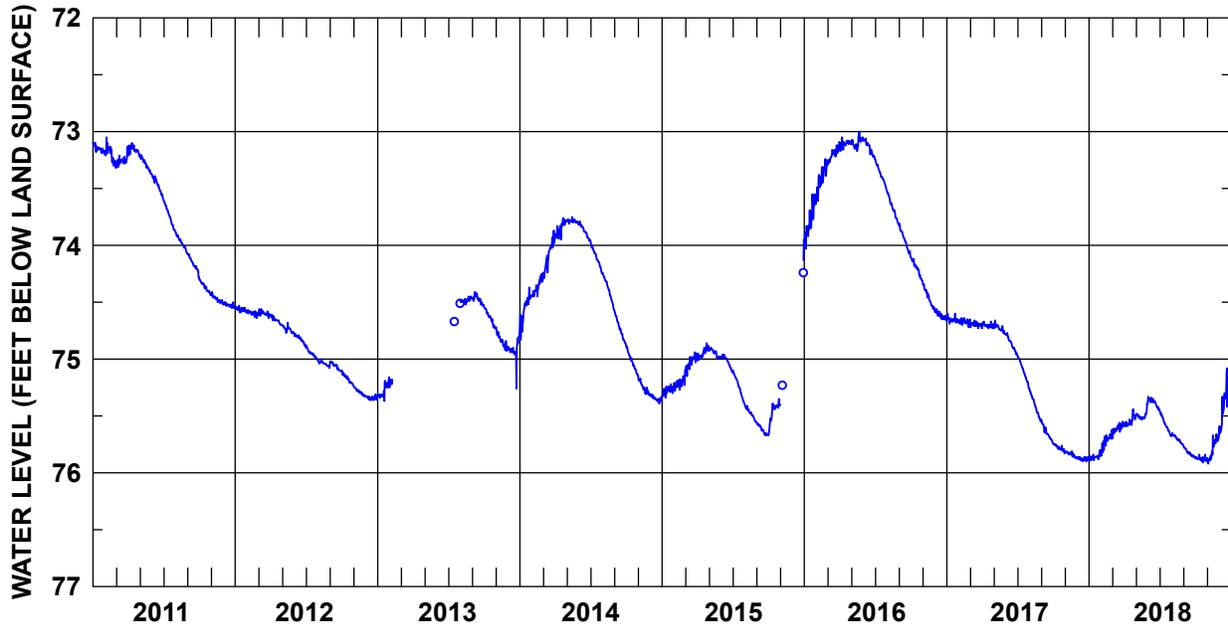

WELL CHARACTERISTICS: Unused domestic well. Depth: 223 ft. Open interval unknown.

LAND SURFACE ELEVATION: 660 ft.

PERIOD OF RECORD: May 2001 through 2018.

EXTREMES: High: 70.36 ft bls (June 30, 2005) Low: 75.92 ft bls (November 3, 2018).

REMARKS: Local topography is flat.

APPENDIX B

Groundwater Levels in the Surficial Aquifer 2011–2018

COUNTY: Allendale

WELL NUMBER: ALL-0372

AQUIFER: Surficial

LATITUDE / LONGITUDE: 33.02482° / -81.38456°

LOCATION: Allendale, 3.5 miles west (SCDNR cluster site C-10).

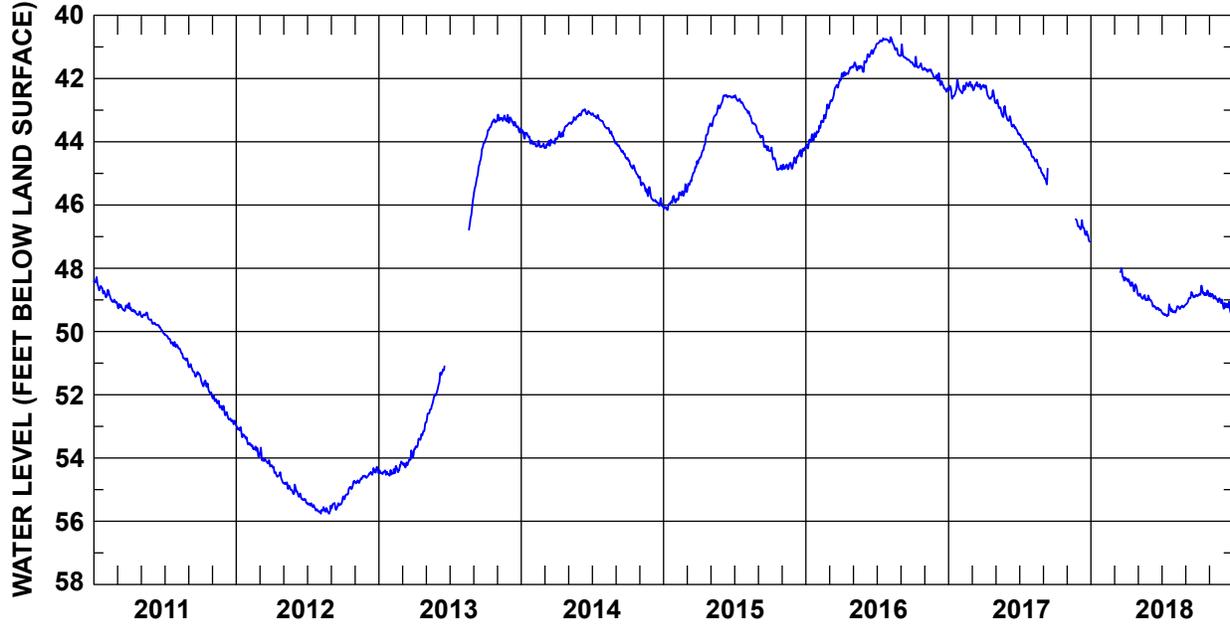

WELL CHARACTERISTICS: Observation well. Depth: 155 ft. Screened from 140 to 150 ft.

LAND SURFACE ELEVATION: 281 ft.

PERIOD OF RECORD: August 1996 through 2018.

EXTREMES: High: 38.14 ft bls (June 3, 1998) Low: 59.77 ft bls (January 30, 2003).

REMARKS: Well previously considered to be screened in Upper Floridan aquifer.

COUNTY: Sumter
 AQUIFER: Surficial

WELL NUMBER: SUM-0355
 LATITUDE / LONGITUDE: 34.01653° / -80.40221°

LOCATION: Dalzell (Ebenezer Elementary School).

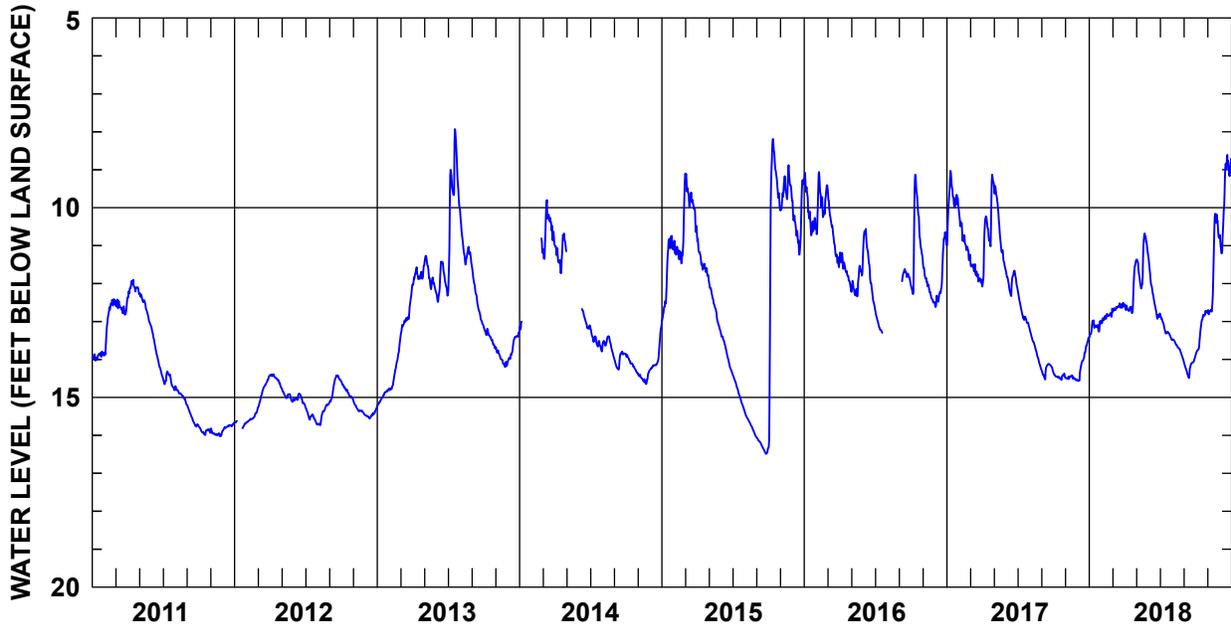

WELL CHARACTERISTICS: Observation well. Depth: 47 ft. Open interval unknown.

LAND SURFACE ELEVATION: 199 ft.

PERIOD OF RECORD: August 2003 through 2018.

EXTREMES: High: 7.93 ft bls (July 19, 2013) Low: 16.49 ft bls (September 25, 2015).

REMARKS: Well may be partially screened in Crouch Branch aquifer. Measured by USGS since September 2016.

APPENDIX C

Groundwater Levels in the Gramling and Charleston Aquifers 2011–2018

COUNTY: Allendale

WELL NUMBER: ALL-0348

AQUIFER: Gramling confining unit

LATITUDE / LONGITUDE: 33.02499° / -81.38475°

LOCATION: Allendale, 3.5 miles west (SCDNR cluster site C-10).

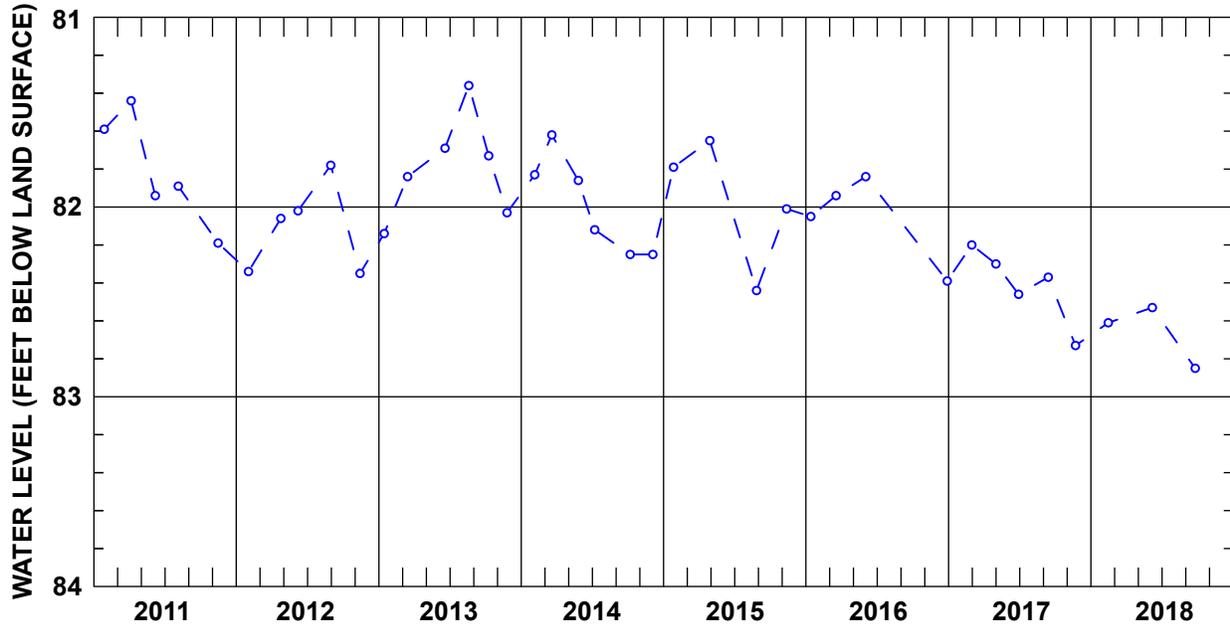

WELL CHARACTERISTICS: Observation well. Depth: 1,605 ft. Screened from 1,575 to 1,600 ft.

LAND SURFACE ELEVATION: 280 ft.

PERIOD OF RECORD: October 1996 through 2018.

EXTREMES: High: 79.05 ft bls (February 5, 1998) Low: 82.85 ft bls (September 25, 2018).

REMARKS: Only manual measurements after May 2004.

COUNTY: Beaufort

WELL NUMBER: BFT-2055

AQUIFER: Gramling and Charleston aquifers

LATITUDE / LONGITUDE: 32.19138° / -80.70385°

LOCATION: Hilton Head Island.

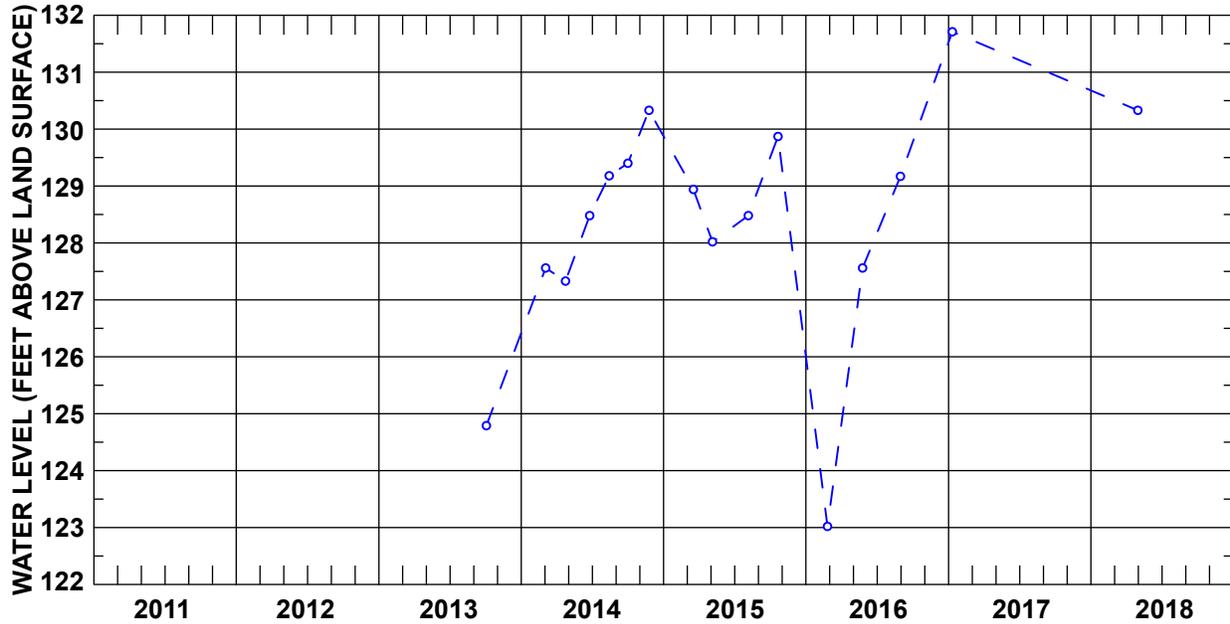

WELL CHARACTERISTICS: Unused test well. Depth: 3,708 ft. Screened from 2,782 to 3,688 ft.

LAND SURFACE ELEVATION: 11 ft.

PERIOD OF RECORD: April 2000 through 2018.

EXTREMES: High: 155.90 ft als (April 1, 2000) Low: 123.02 ft als (February 25, 2016).

REMARKS: Flowing well. Manual measurements only.

COUNTY: Dillon

WELL NUMBER: DIL-0171

AQUIFER: Gramling confining unit

LATITUDE / LONGITUDE: 34.33027° / -79.28692°

LOCATION: Dillon, 6.5 miles southeast (Little Pee Dee State Park).

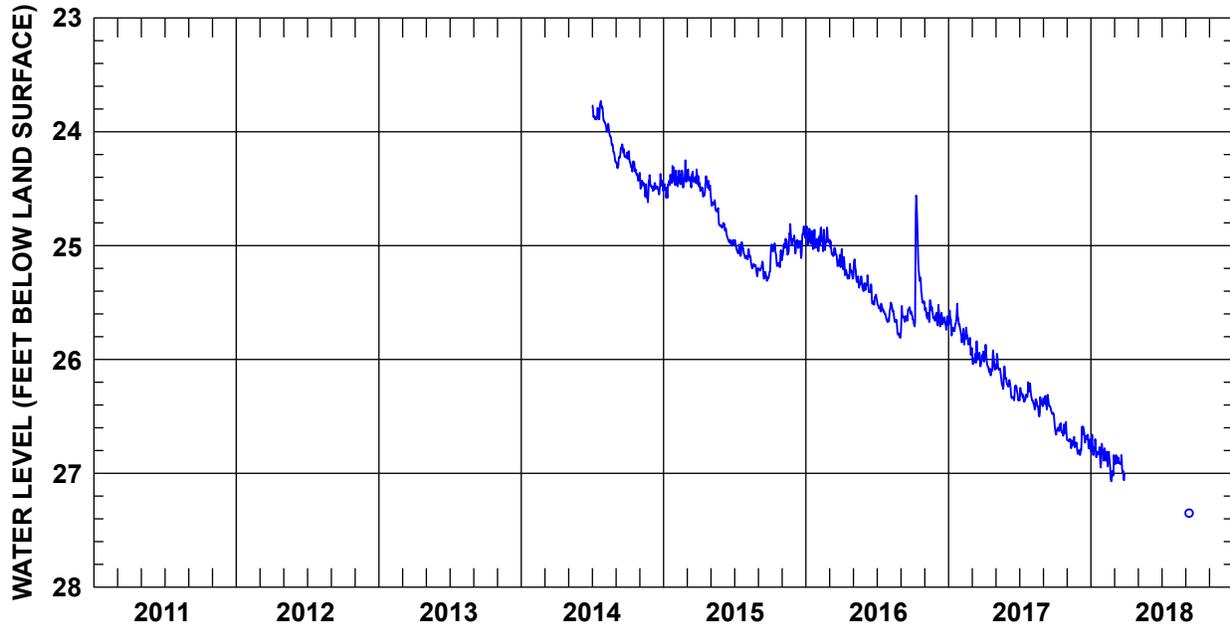

WELL CHARACTERISTICS: Observation well. Depth: 555 ft. Screened from 540 to 550 ft.

LAND SURFACE ELEVATION: 82 ft.

PERIOD OF RECORD: July 2014 through 2018.

EXTREMES: High: 23.73 ft bls (July 24, 2014) Low: 27.07 ft bls (February 22 and 23, 2018).

COUNTY: Horry

WELL NUMBER: HOR-0973

AQUIFER: Gramling

LATITUDE / LONGITUDE: 33.72265° / -78.90305°

LOCATION: Myrtle Beach (Myrtle Beach Surface Water Treatment Plant).

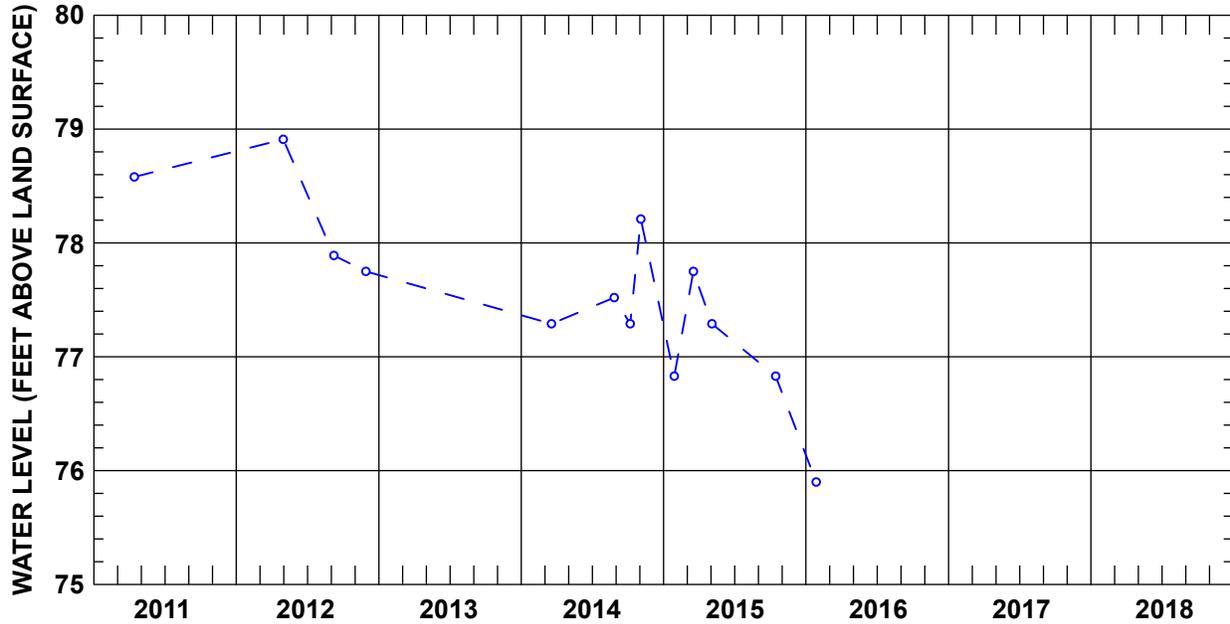

WELL CHARACTERISTICS: Unused test well. Depth: 1,331 ft. Screened from 1,012 to 1,328 ft.

LAND SURFACE ELEVATION: 15 ft.

PERIOD OF RECORD: August 1999 to January 2016.

EXTREMES: **High:** 85.69 ft als (November 4, 1999) **Low:** 75.90 ft als (January 27, 2016).

REMARKS: Flowing well. Manual measurements only. Unable to measure water pressure since early 2016.

COUNTY: Jasper

WELL NUMBER: JAS-0426

AQUIFER: Charleston

LATITUDE / LONGITUDE: 32.61820° / -80.99539°

LOCATION: Ridgeland, 9 miles north-northwest (SCDNR cluster site C-15).

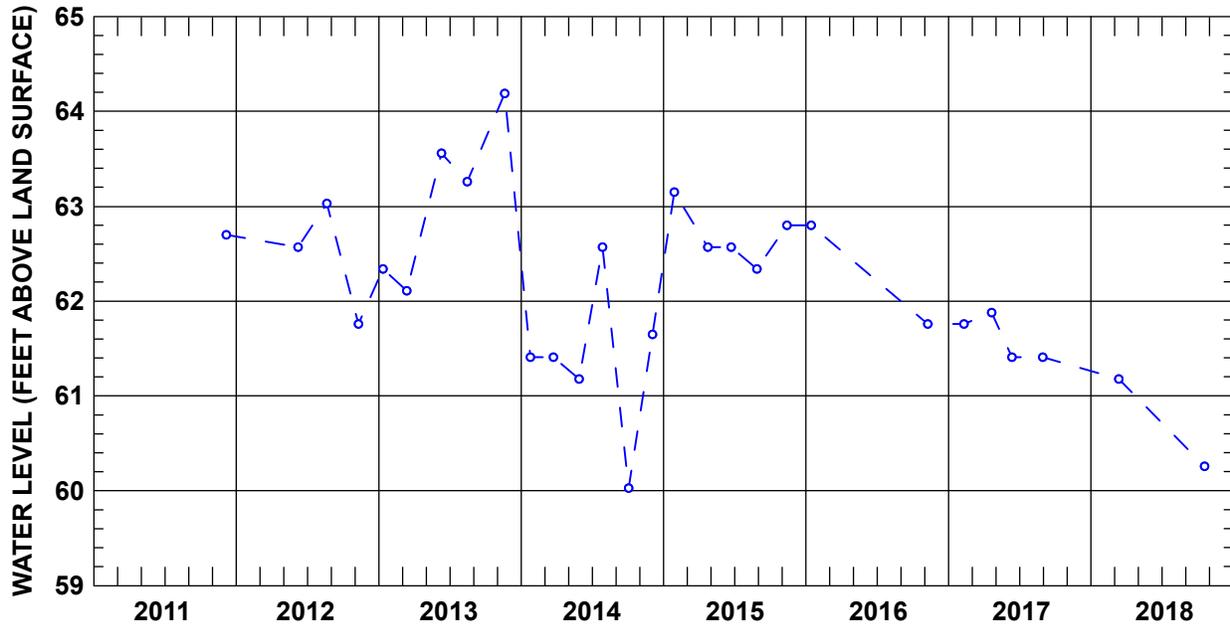

WELL CHARACTERISTICS: Observation well. Depth: 1,994 ft. Screened from 1,949 to 1,994 ft.

LAND SURFACE ELEVATION: 62 ft.

PERIOD OF RECORD: April 2000 through 2018.

EXTREMES: High: 79.56 ft als (April 17, 2000) Low: 60.03 ft als (October 3, 2014).

REMARKS: Flowing well. Manual measurements only.

COUNTY: Marion
AQUIFER: Gramling

WELL NUMBER: MRN-0078
LATITUDE / LONGITUDE: 33.86178° / -79.33030°

LOCATION: Brittons Neck, 3 miles south (former Brittons Neck Fire Tower).

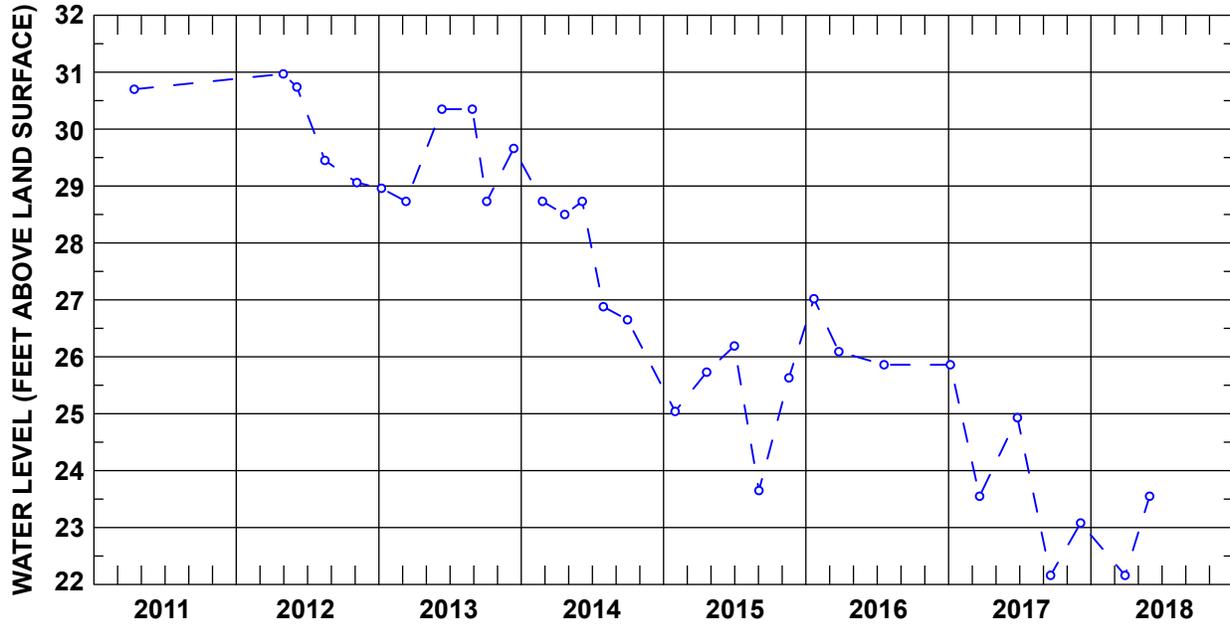

WELL CHARACTERISTICS: Observation well. Depth: 1,038 ft. Screened from 1,008 to 1,028 ft.

LAND SURFACE ELEVATION: 34 ft.

PERIOD OF RECORD: August 1999 through 2018.

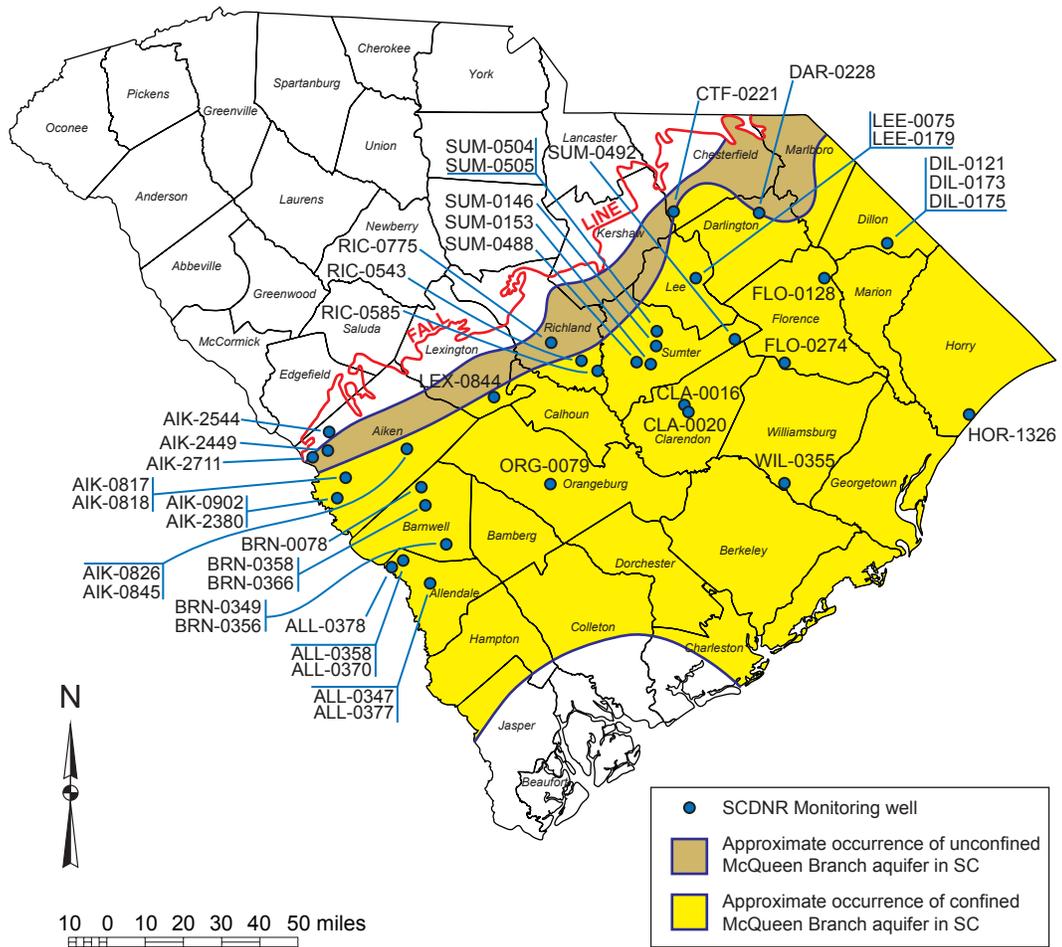

EXTREMES: High: 43.02 ft als (March 30, 2001) Low: 22.16 ft als (September 19, 2017 and March 29, 2018).

REMARKS: Flowing well. Manual measurements only.

APPENDIX D

Groundwater Levels in the McQueen Branch Aquifer 2011–2018

COUNTY: Aiken

WELL NUMBER: AIK-0817

AQUIFER: McQueen Branch

LATITUDE / LONGITUDE: 33.43785° / -81.77037°

LOCATION: New Ellenton, 4 miles west-southwest (SCDNR cluster site C-2).

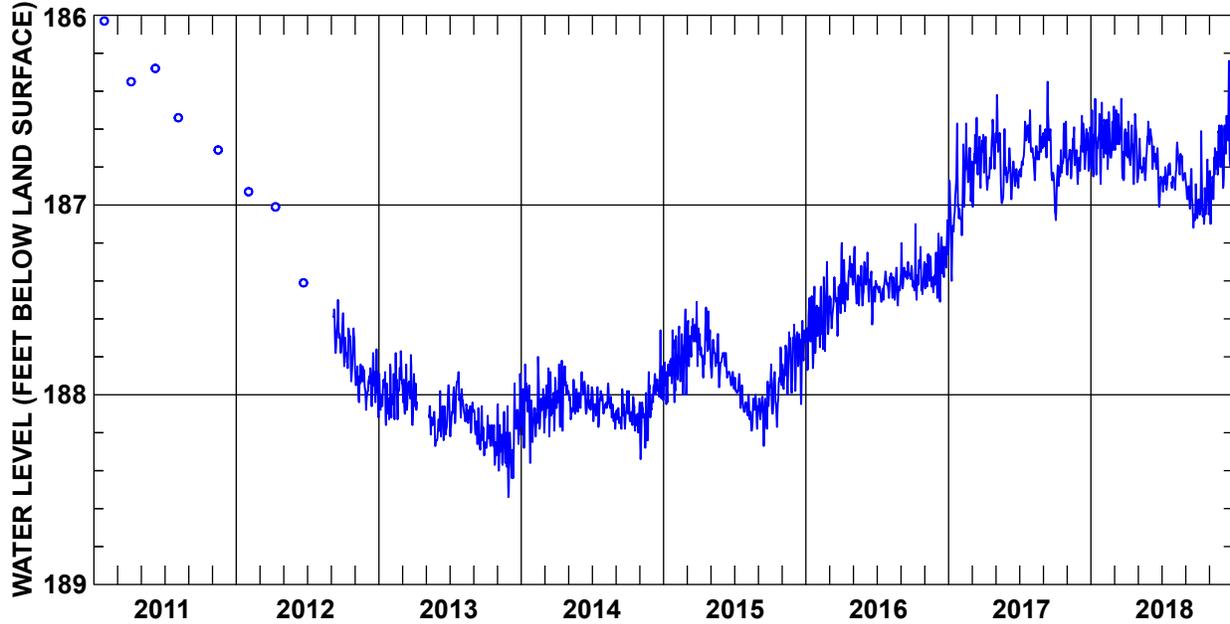

WELL CHARACTERISTICS: Observation well. Depth: 535 ft. Screened from 520 to 530 ft.

LAND SURFACE ELEVATION: 418 ft.

PERIOD OF RECORD: April 1988 through 2018.

EXTREMES: High: 179.65 ft bls (February 2, 1999) Low: 188.54 ft bls (November 29, 2013).

REMARKS: No data from October 2000 to April 2006. Only manual measurements April 2006 to September 2012.

COUNTY: Aiken

WELL NUMBER: AIK-2711

AQUIFER: McQueen Branch

LATITUDE / LONGITUDE: 33.51377° / -81.92097°

LOCATION: North Augusta, 2.5 miles east-northeast.

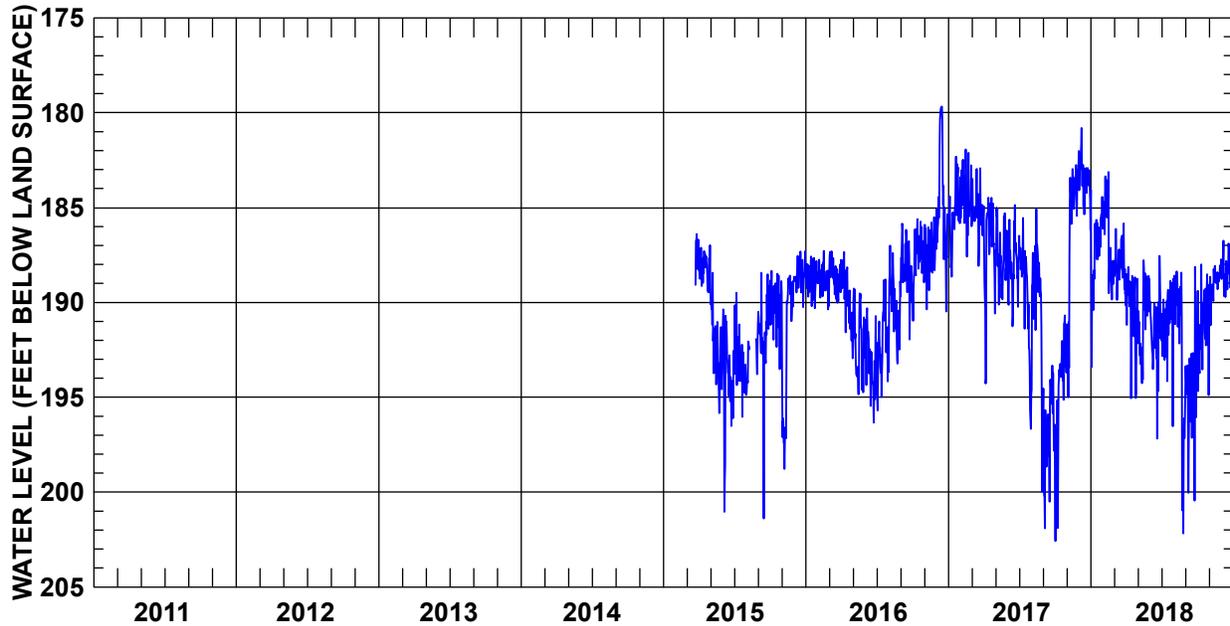

WELL CHARACTERISTICS: Observation well. Depth: unknown. Screened from 209 to 239 ft.

LAND SURFACE ELEVATION: 427 ft.

PERIOD OF RECORD: March 2015 through 2018.

EXTREMES: High: 179.67 ft bls (December 15, 2016) Low: 202.57 ft bls (October 2, 2017).

REMARKS: Located near active public supply well.

COUNTY: Barnwell

WELL NUMBER: BRN-0355

AQUIFER: Crouch Branch

LATITUDE / LONGITUDE: 33.17899° / -81.31439°

LOCATION: Barnwell, 4 miles southeast (SCDNR cluster site C-6).

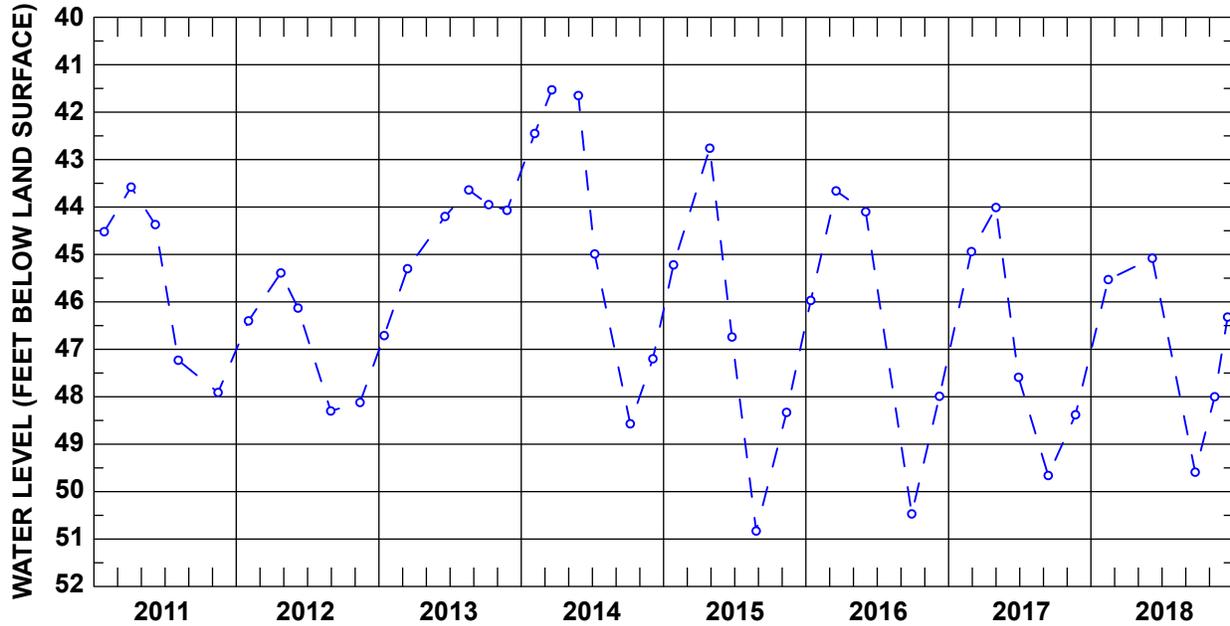

WELL CHARACTERISTICS: Observation well. Depth: 701 ft. Screened from 686 to 696 ft.

LAND SURFACE ELEVATION: 207 ft.

PERIOD OF RECORD: October 1989 through 2018.

EXTREMES: High: 32.54 ft bls (April 21, 1993) Low: 50.83 ft bls (August 26, 2015).

REMARKS: No measurements from August 2000 to January 2006. Only manual measurements since 2006.

COUNTY: Barnwell

WELL NUMBER: BRN-0365

AQUIFER: Crouch Branch

LATITUDE / LONGITUDE: 33.32160° / -81.40680°

LOCATION: Williston, 3.5 miles south (SCDNR cluster site C-5).

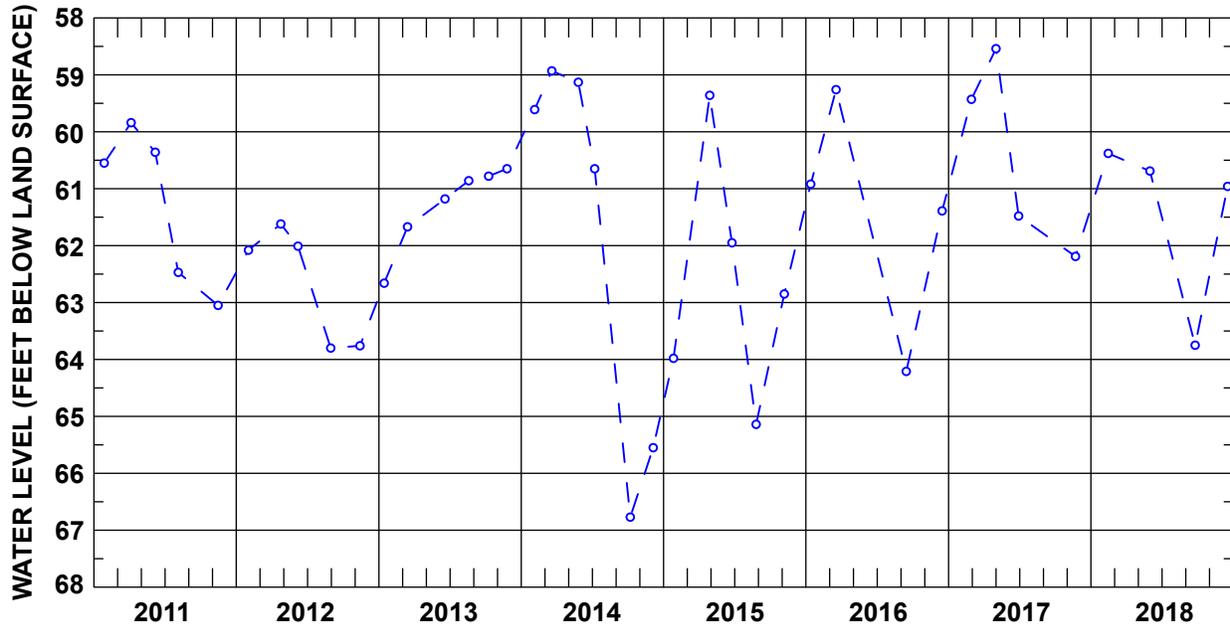

WELL CHARACTERISTICS: Observation well. Depth: 539 ft. Screened from 524 to 534 ft.

LAND SURFACE ELEVATION: 263 ft.

PERIOD OF RECORD: May 1993 through 2018.

EXTREMES: High: 51.57 ft bls (May 23, 1993) Low: 66.77 ft bls (October 7, 2014).

REMARKS: No measurements from July 1999 to April 2006. Only manual measurements since 2006.

COUNTY: Barnwell

WELL NUMBER: BRN-0368

AQUIFER: Crouch Branch

LATITUDE / LONGITUDE: 33.32145° / -81.40680°

LOCATION: Williston, 3.5 miles south (SCDNR cluster site C-5).

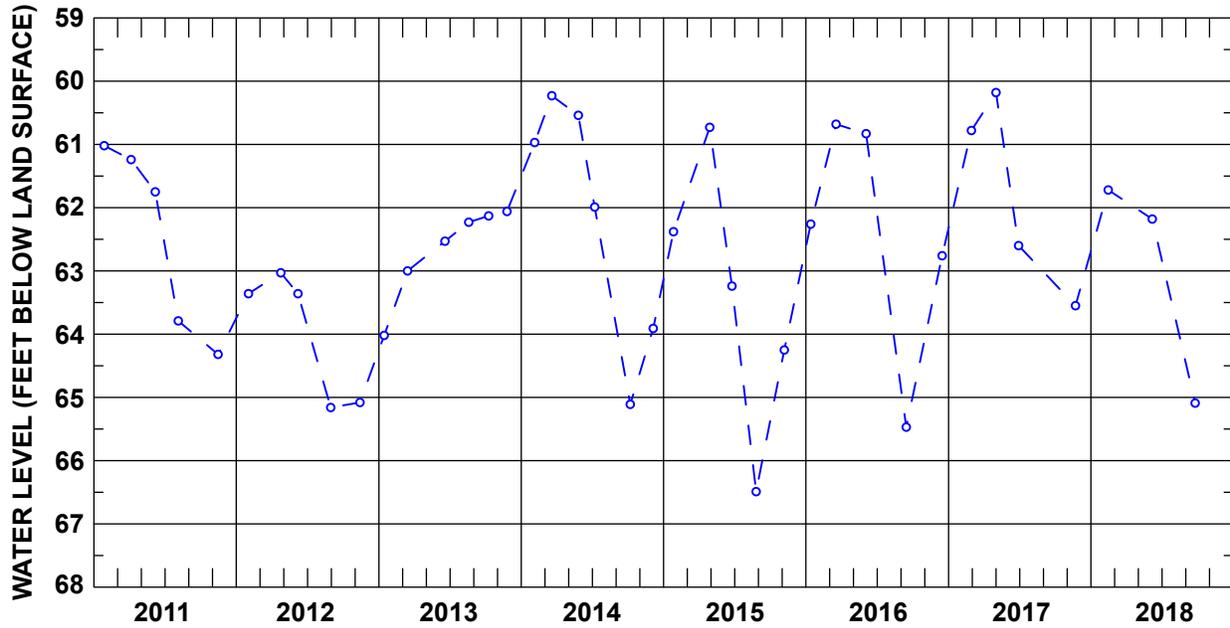

WELL CHARACTERISTICS: Observation well. Depth: 443 ft. Screened from 428 to 438 ft.

LAND SURFACE ELEVATION: 264 ft.

PERIOD OF RECORD: May 1993 through 2018.

EXTREMES: High: 53.13 ft bls (May 21, 1993) Low: 66.49 ft bls (August 26, 2015).

REMARKS: No measurements from July 1999 to April 2006. Only manual measurements since 2006.

COUNTY: Calhoun

WELL NUMBER: CAL-0194

AQUIFER: Crouch Branch

LATITUDE / LONGITUDE: 33.59858° / -80.64786°

LOCATION: Creston (Fire Station).

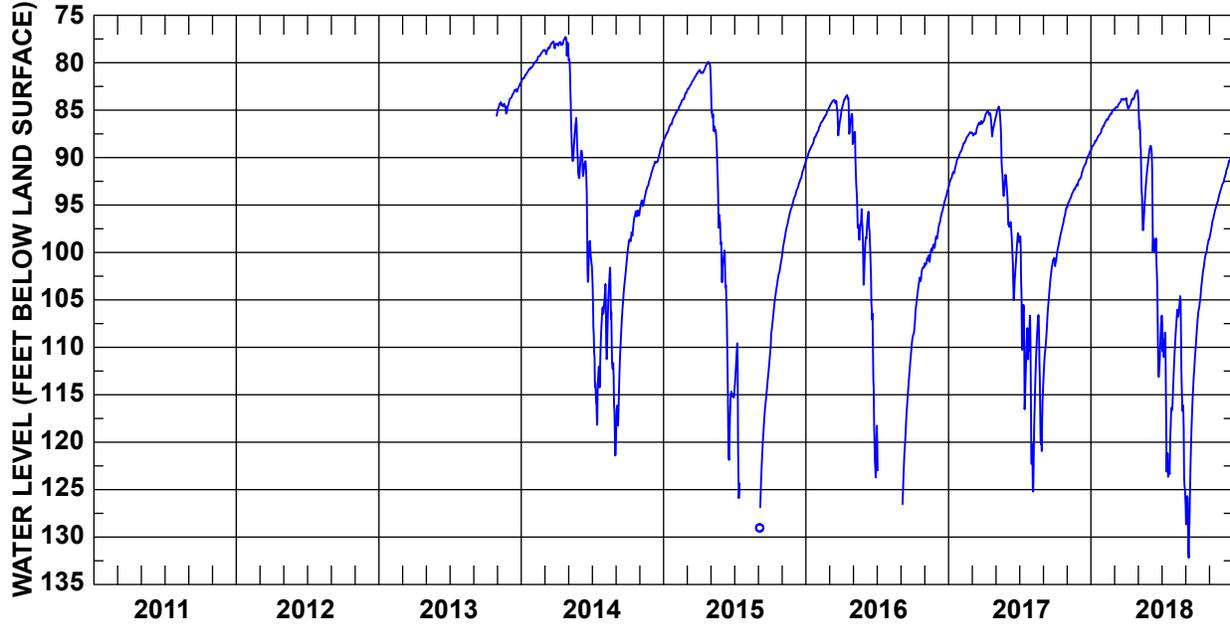

WELL CHARACTERISTICS: Observation well. Depth: 254 ft. Screened from 239 to 249 ft.

LAND SURFACE ELEVATION: 190 ft.

PERIOD OF RECORD: October 2013 through 2018.

EXTREMES: High: 77.28 ft bls (April 25, 2014) Low: 132.19 ft bls (September 9, 2018).

REMARKS: Water level dropped below recorder during summers of 2015 and 2016.

† This value occurred on more than one day in that year. The date of the first occurrence is reported.

COUNTY: Charleston

WELL NUMBER: CHN-0803

AQUIFER: Gordon

LATITUDE / LONGITUDE: 33.15578° / -79.36386°

LOCATION: McClellanville, 7 miles northeast (Santee Coastal Reserve).

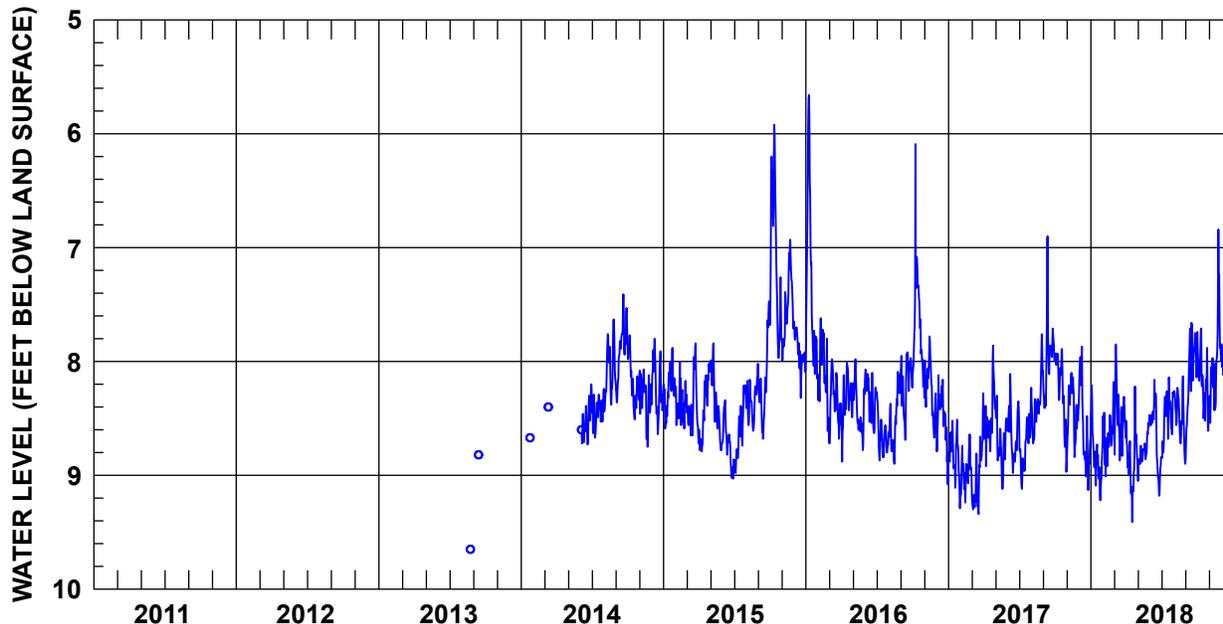

WELL CHARACTERISTICS: Observation well. Depth: 112 ft. Screened from 48 to 112 ft.

LAND SURFACE ELEVATION: 10 ft.

PERIOD OF RECORD: June 2000 through 2018.

EXTREMES: High: 5.66 ft bls (January 9, 2016) Low: 9.65 ft bls (August 23, 2013).

REMARKS: Conductivity also measured in this well. Hydraulic connection to South Santee River.

† This value occurred on more than one day in that year. The date of the first occurrence is reported.

COUNTY: Hampton
 AQUIFER: Gordon
 LOCATION: Furman.

WELL NUMBER: HAM-0050
 LATITUDE / LONGITUDE: 32.67979° / -81.18712°

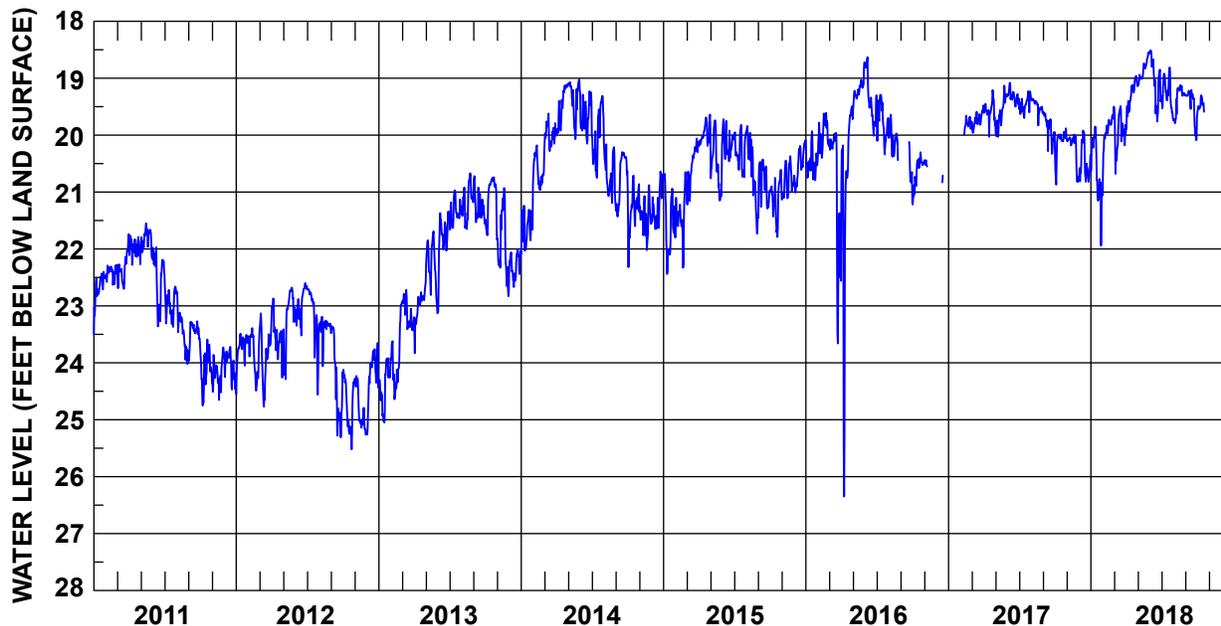

WELL CHARACTERISTICS: Unused public supply well. Depth: 968 ft. Open interval unknown.

LAND SURFACE ELEVATION: 114 ft.

PERIOD OF RECORD: January 2001 through 2018.

EXTREMES: High: 18.51 ft bls (June 3, 2018) Low: 26.73 ft bls (June 1, 2002).

REMARKS: Well construction uncertain; may be open to other aquifers.

APPENDIX G

Groundwater Levels in the Floridan Aquifer 2011–2018

Upper Floridan Aquifer

Middle Floridan Aquifer

COUNTY: Allendale

WELL NUMBER: ALL-0363

AQUIFER: Upper Floridan

LATITUDE / LONGITUDE: 33.11376° / -81.50619°

LOCATION: Millet, 3 miles northeast (SCDNR cluster site C-7).

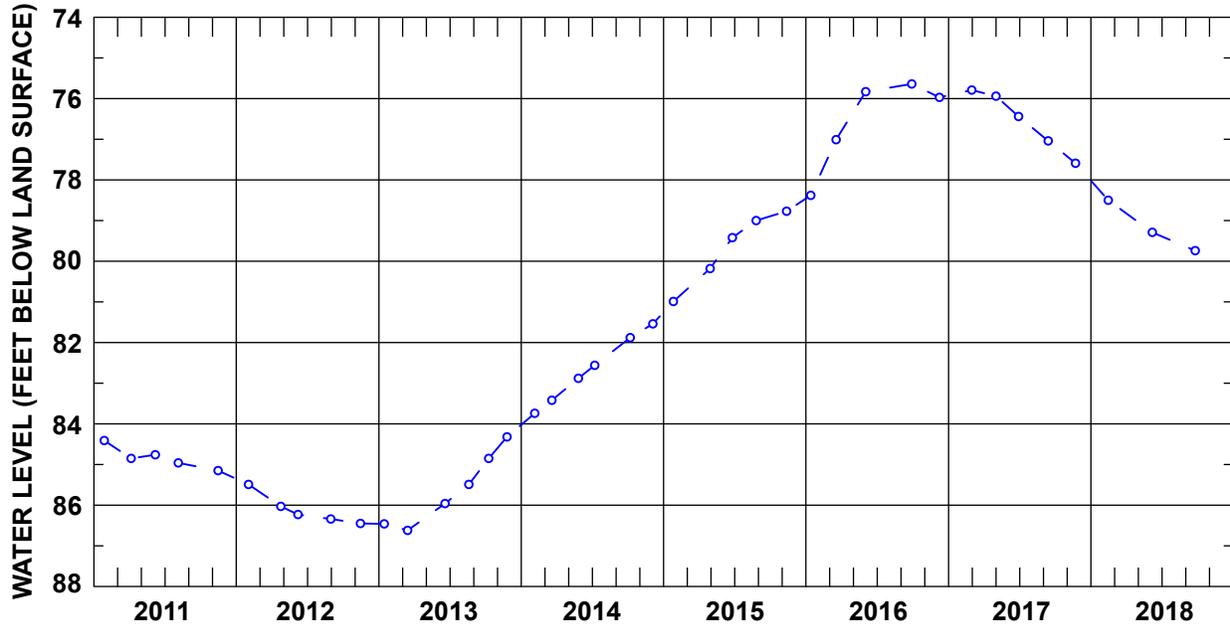

WELL CHARACTERISTICS: Observation well. Depth: 105 ft. Screened from 90 to 100 ft.

LAND SURFACE ELEVATION: 245 ft.

PERIOD OF RECORD: November 1995 through 2018.

EXTREMES: High: 68.34 ft bls (June 14, 1998) Low: 86.62 ft bls (March 15, 2013).

REMARKS: Only manual measurements after November 2001.

COUNTY: Allendale

WELL NUMBER: ALL-0364

AQUIFER: Middle Floridan

LATITUDE / LONGITUDE: 33.11363° / -81.50615°

LOCATION: Millet, 3 miles northeast (SCDNR cluster site C-7).

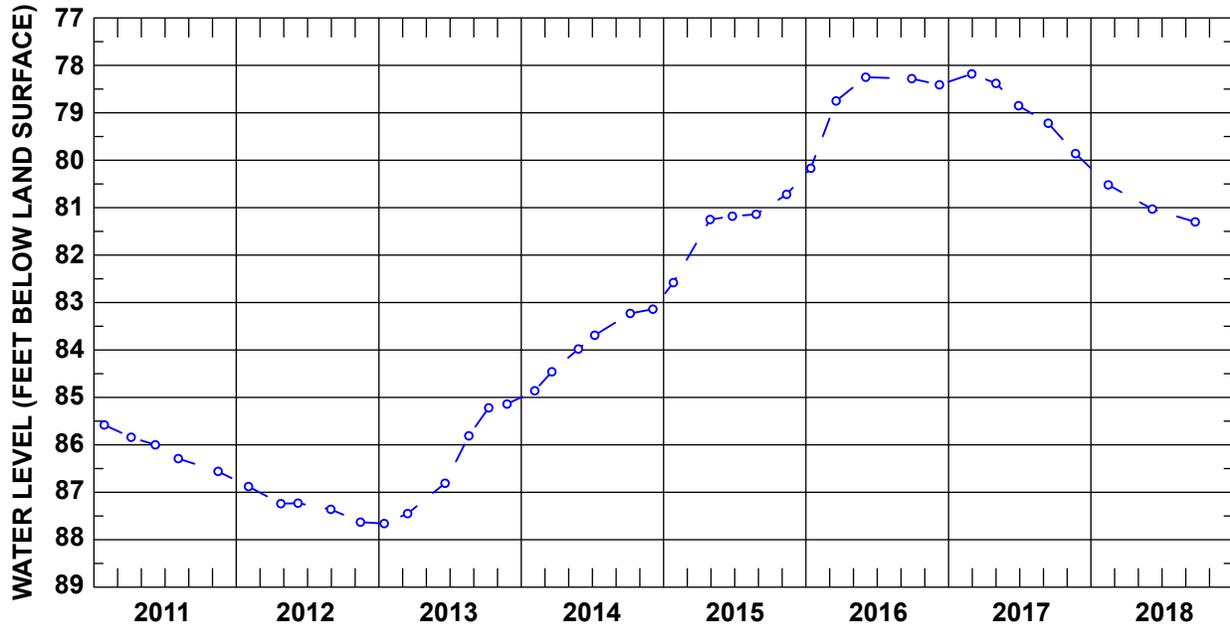

WELL CHARACTERISTICS: Observation well. Depth: 225 ft. Screened from 210 to 220 ft.

LAND SURFACE ELEVATION: 244 ft.

PERIOD OF RECORD: November 1995 through 2018.

EXTREMES: High: 71.90 ft bls (May 8, 1998) Low: 87.66 ft bls (January 14, 2013).

REMARKS: Only manual measurements after January 2002.

COUNTY: Allendale

WELL NUMBER: ALL-0371

AQUIFER: Upper Floridan

LATITUDE / LONGITUDE: 33.02484° / -81.38469°

LOCATION: Allendale, 3.5 miles west (SCDNR cluster site C-10).

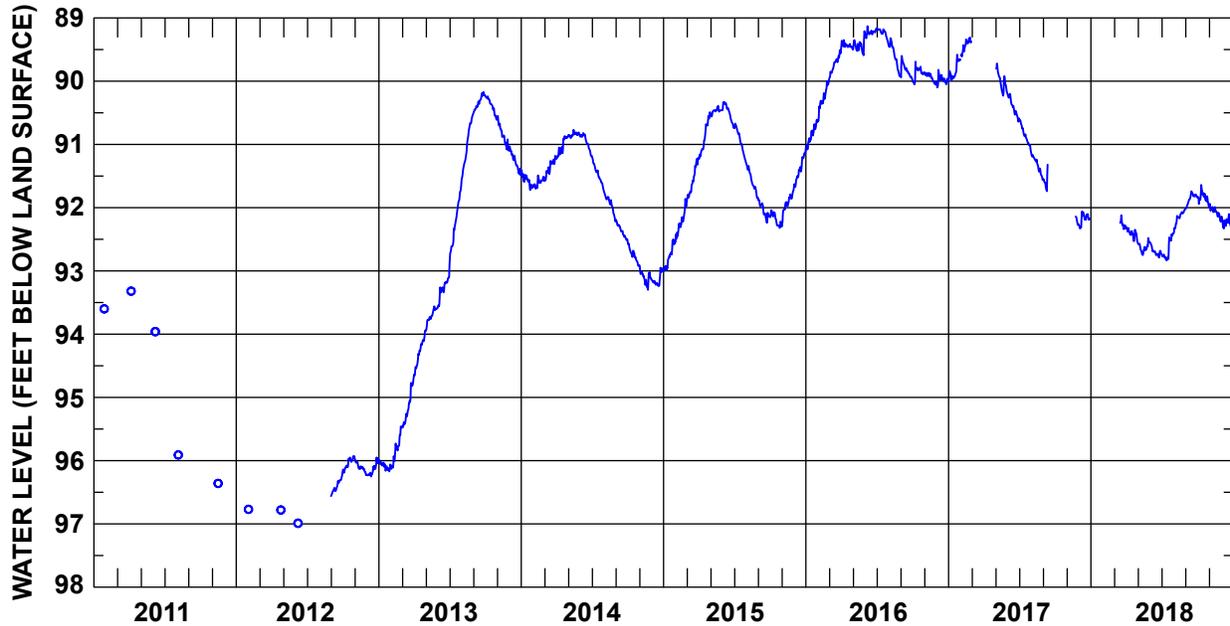

WELL CHARACTERISTICS: Observation well. Depth: 217 ft. Screened from 192 to 212 ft.

LAND SURFACE ELEVATION: 281 ft.

PERIOD OF RECORD: August 1996 through 2018.

EXTREMES: High: 85.46 ft bls (May 10, 1998) Low: 100.11 ft bls (November 8, 2002).

REMARKS: Only manual measurements from June 2004 to September 2012.

WELL NUMBER: ORG-0431

AQUIFER: Middle Floridan

LATITUDE / LONGITUDE: 33.50827° / -80.86493°

LOCATION: Orangeburg (Clark Middle School).

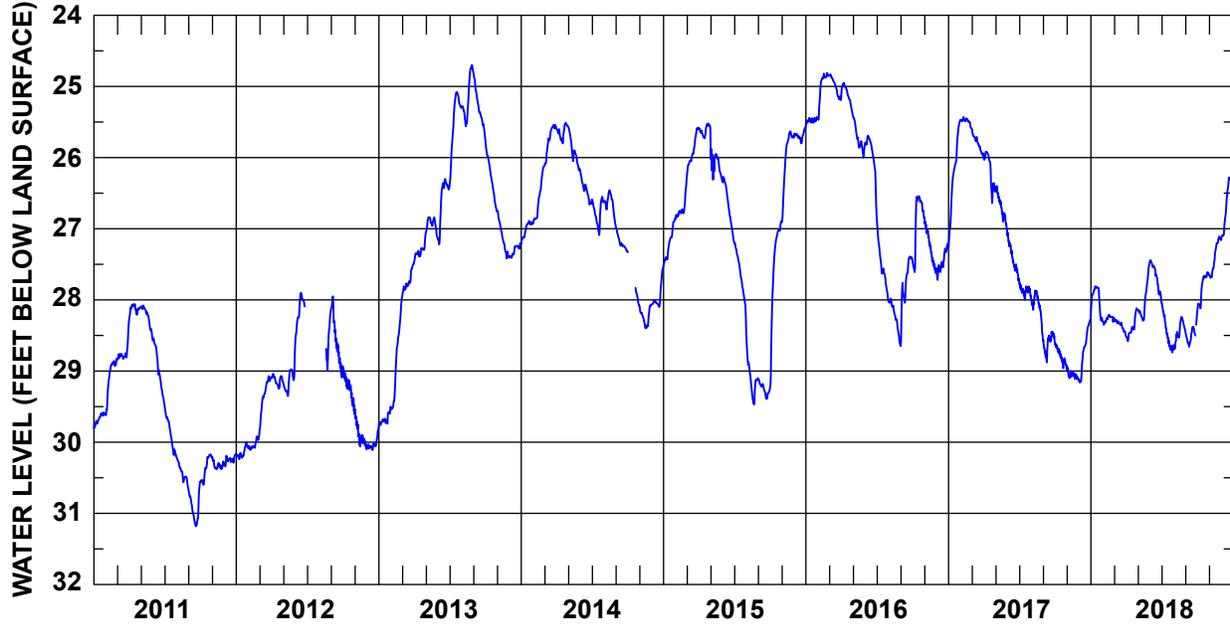

WELL CHARACTERISTICS: Observation well. Depth: 93 ft. Screened from 83 to 88 ft.

LAND SURFACE ELEVATION: 256 ft.

PERIOD OF RECORD: March 2001 through 2018.

EXTREMES: High: 24.70 ft bls (August 27 and 28, 2013) Low: 33.82 ft bls (September 25, 2002).

† This value occurred on more than one day in that year. The date of the first occurrence is reported.

COUNTY: Orangeburg

WELL NUMBER: ORG-0634

AQUIFER: Middle Floridan

LATITUDE / LONGITUDE: 33.45434° / -80.71843°

LOCATION: Orangeburg, 7 miles east-southeast (Fire Station).

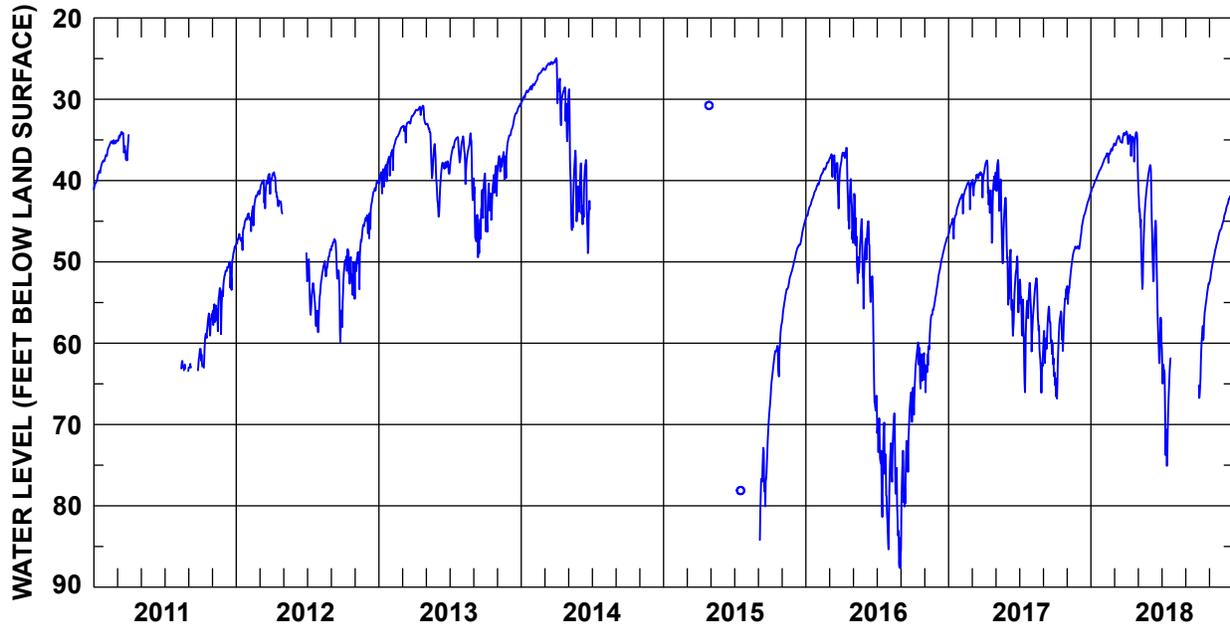

WELL CHARACTERISTICS: Observation well. Depth: 256 ft. Open hole below 228 ft.

LAND SURFACE ELEVATION: 163 ft.

PERIOD OF RECORD: June 2009 through 2018.

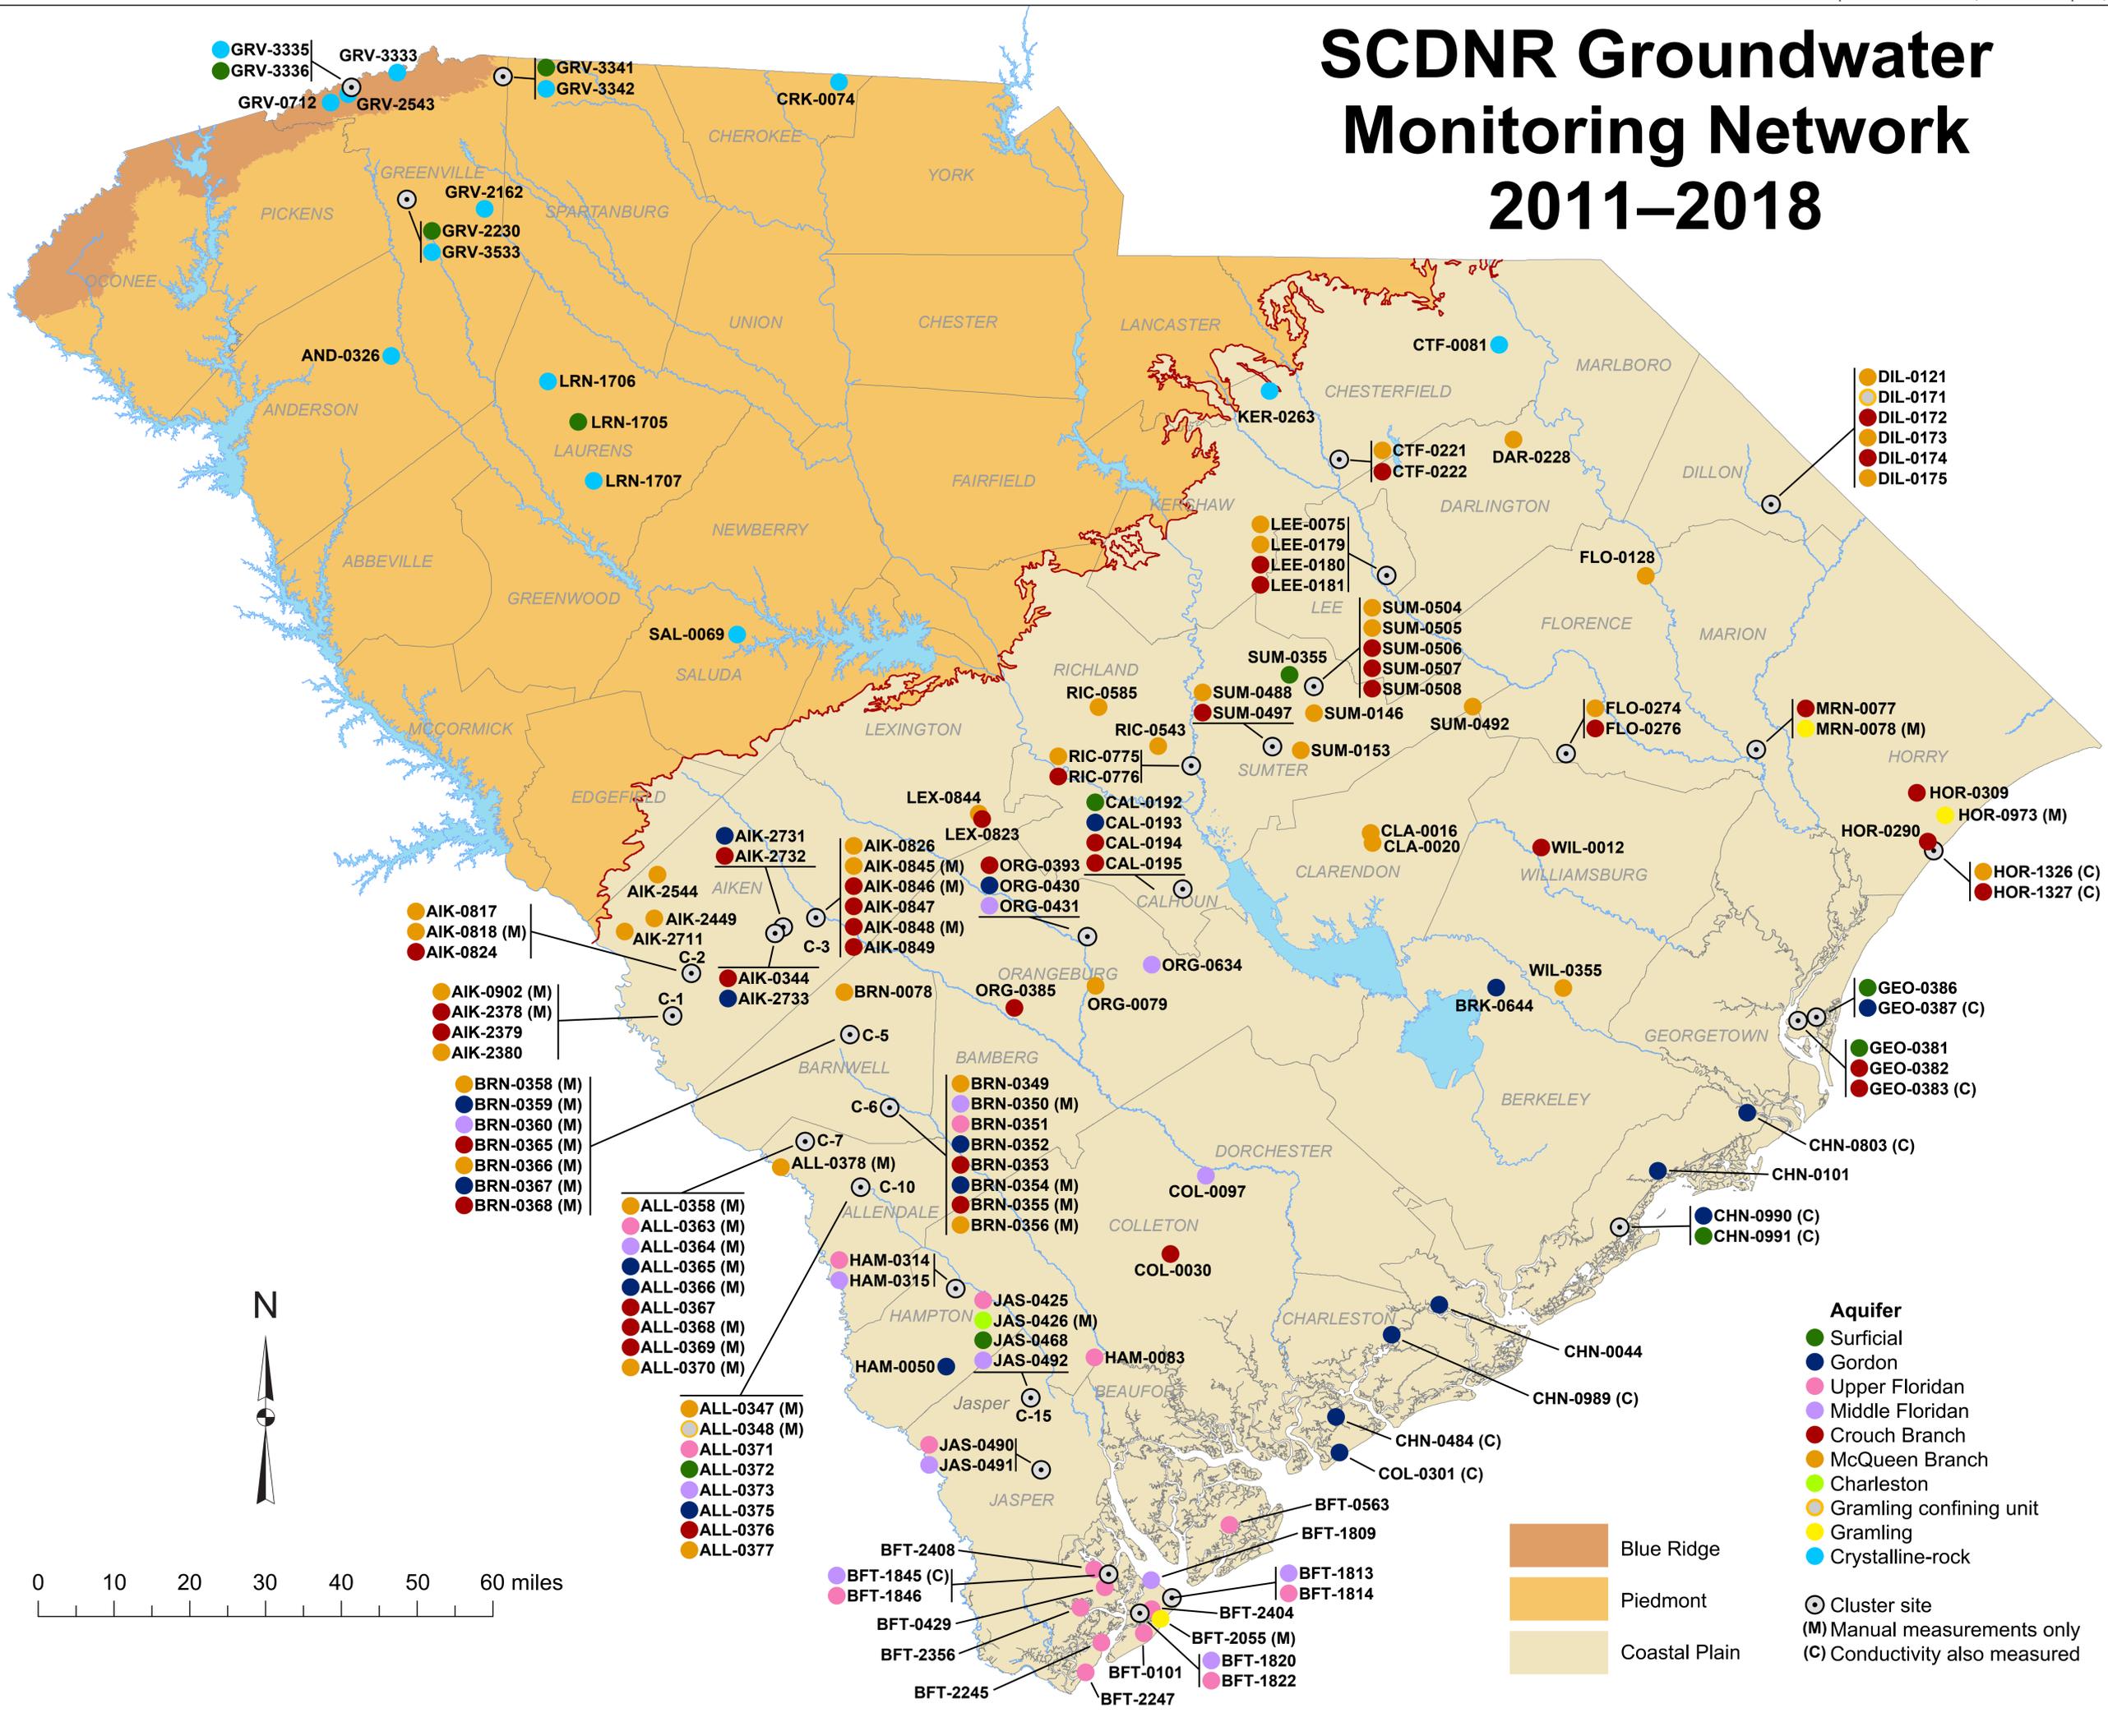

EXTREMES: High: 24.95 ft bls (April 1, 2014) Low: 87.64 ft bls (August 30, 2016).
