Well cluster construction data.....	7
-------------------------------------	---

INTRODUCTION

The South Carolina Water Resources Commission (SCWRC), in its continuing efforts to acquire water-resource information for all parts of the State, and being aware of the deficiency of detailed geologic and hydrologic data for the area surrounding the Savannah River Plant (SRP), began a geohydrologic investigation in part of the Lower Savannah River Project Area in 1986. The area, consisting of Aiken, Allendale, and Barnwell Counties in western South Carolina, lies almost entirely within the Coastal Plain physiographic province. The framework for the investigation is centered on a well cluster system, an extension of the well cluster system being constructed on the plant site as a part of the "SRP Baseline Hydrogeologic Investigation" (Bledsoe, 1984, 1987). The format of the information obtained is compatible with that of the SRP project.

The entire well cluster project, as originally proposed, consists of ten well cluster sites, of five to ten wells each, located peripheral to SRP (Fig. 1). The well cluster sites C-2 and C-6 were selected as part of Phase I activities. Phase II well cluster sites (C-3 and C-5) were selected on the basis of the preliminary data obtained during Phase I. The locations of the remaining sites are tentative and will be based on the data obtained during Phases I and II. Budget constraints necessitated a modification of the original planned activities and expenditures. The Savannah River Operations Office and SCWRC agreed that the available funds could best be used by coring two deep wells and completing two shallow

Figure 1. Location of well-cluster network.

wells annually for the first two years of the project. It was decided that Phase I core holes (C-2 and C-6) would provide the most useful data initially. Phase I of the project consisted of continuous coring, geophysical logging, physical testing of sediment samples, and the construction of five permanent observation wells at the two sites. Drilling operations began in October 1986 and were completed in August 1987 (Logan, 1987). Prior to work on Phase II, additional funds were allocated to complete all of the wells at cluster sites C-2 and C-6.

SCOPE OF WORK FOR PHASE II

Phase II of the project consisted of continuous coring, geophysical logging, physical testing of sediment samples, and the construction of four permanent observation wells at sites C-3 and C-5. Three additional wells were completed at C-2 and five more were constructed at C-6, for a total of twelve wells completed during Phase II. Drilling operations began in January 1988 and were completed in June 1988. In addition, automatic digital recorders (ADR's) and a permanent chain-link fence were installed at sites C-2 and C-6.

METHODOLOGY

Geologic data were obtained by continuously coring one exploratory well at each cluster site from land surface through the Coastal Plain sediments and into the crystalline basement. The core samples were described in the field by SCWRC geologists (Appendices A and B). Cores were wrapped in plastic, labeled in 5-foot intervals, and placed on a

polyvinyl chloride (PVC) tray. The tray was then inserted into a 5-foot section of SCH-40 PVC and capped on both ends. The exploratory well at site C-3 (AIK-826) was cored to a depth of 541 ft (feet) and the well at site C-5 (BRN-357) was cored to a depth of 1,084.5 ft. After coring operations were completed, the borings were geophysically logged by SCWRC. The logs obtained include: natural gamma-ray; single-point resistance; long- and short-normal resistivity; lateral resistivity; spontaneous-potential; and caliper. From examination of the geologic samples and geophysical logs and consultation with geologists from SRP, the aquifers were identified and the appropriate zones for screening were determined. In addition, tentative formation contacts were selected. These contacts will be considered tentative until age dates have been determined by paleontological studies. The borings were then reamed to 12 1/4 inches, and 6-inch galvanized steel casing was set and pressure grouted from 10 ft above the top of the screen setting to land surface. After allowing the grout to set, a 5 5/8-inch hole was drilled to a depth of 25 ft below the bottom of the 6-inch casing. A 10-foot section of 4-inch screen equipped with 5 ft of blank-pipe sump and 35 ft of overlap pipe was installed in the bore hole. The top of the overlap pipe was fitted with a neoprene packer to isolate the screened zone. Typical well-construction design is shown in Figure 2. Wells completed in Phase I and Phase II of the project are all natural-filter designed. This means that a screen size is selected so that most of the material smaller than the screen openings will be removed during development, leaving only the coarser particles. A zone of higher hydraulic conductivity and porosity is thereby created around the well screen. Wire-wound 4-inch well screens with 0.010-inch openings were used in all 12 wells. Wells greater than

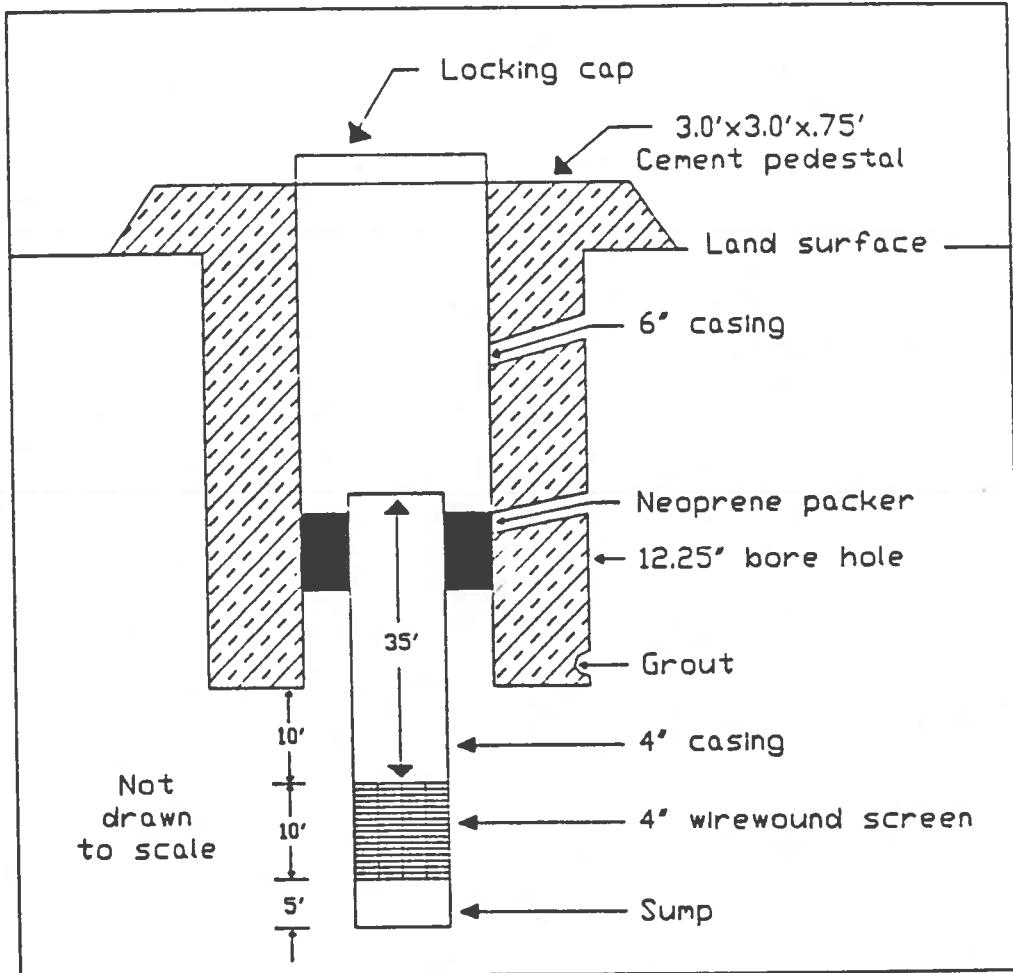

Figure 2. Typical well construction.

300 ft in depth were constructed with standard threaded and coupled Schedule 40 galvanized steel casing and stainless-steel screens. Wells less than 300 ft in depth were constructed with threaded-joint PVC casing and screens. Construction details for each well are given in the Table.

After the screens were installed, the wells were developed by alternately surging and pumping with air. Development continued until a clear, sand-free discharge was obtained.

CLUSTER SITE C-2

Cluster site C-2 is located about 5 miles west northwest of the town of New Ellenton, S.C., and 15 miles northwest of the center of SRP (Fig. 3). The land surface elevation is approximately 420 ft m.s.l. Two wells (AIK-817 and AIK-818) were installed in the cluster as a part of Phase I activities, and three additional wells were added in Phase II. The well layout for cluster C-2 is shown in Figure 4.

The three additional wells drilled in Phase II are wells AIK-823, AIK-824, and AIK-825. AIK-823 was drilled to a total depth of 168 ft (+247 ft m.s.l.) and screened in the Congaree Formation between 153 and 163 ft (+262 to +252 ft m.s.l.). This well did not yield water. AIK-824 was drilled to a total depth of 365 ft (+55 ft m.s.l.) and screened in the Black Creek Formation between 350 and 360 ft (+70 to +60 ft m.s.l.). The last well (AIK-825) was drilled to a total depth of 230 ft (+190 ft m.s.l.) and screened in the PeeDee Formation between 216 and 226 ft (+204 to +194 ft m.s.l.). The screened zones and water levels obtained at

L All depth measurements in feet below land surface.

2 Elevations estimated from topographic maps until surveyed.

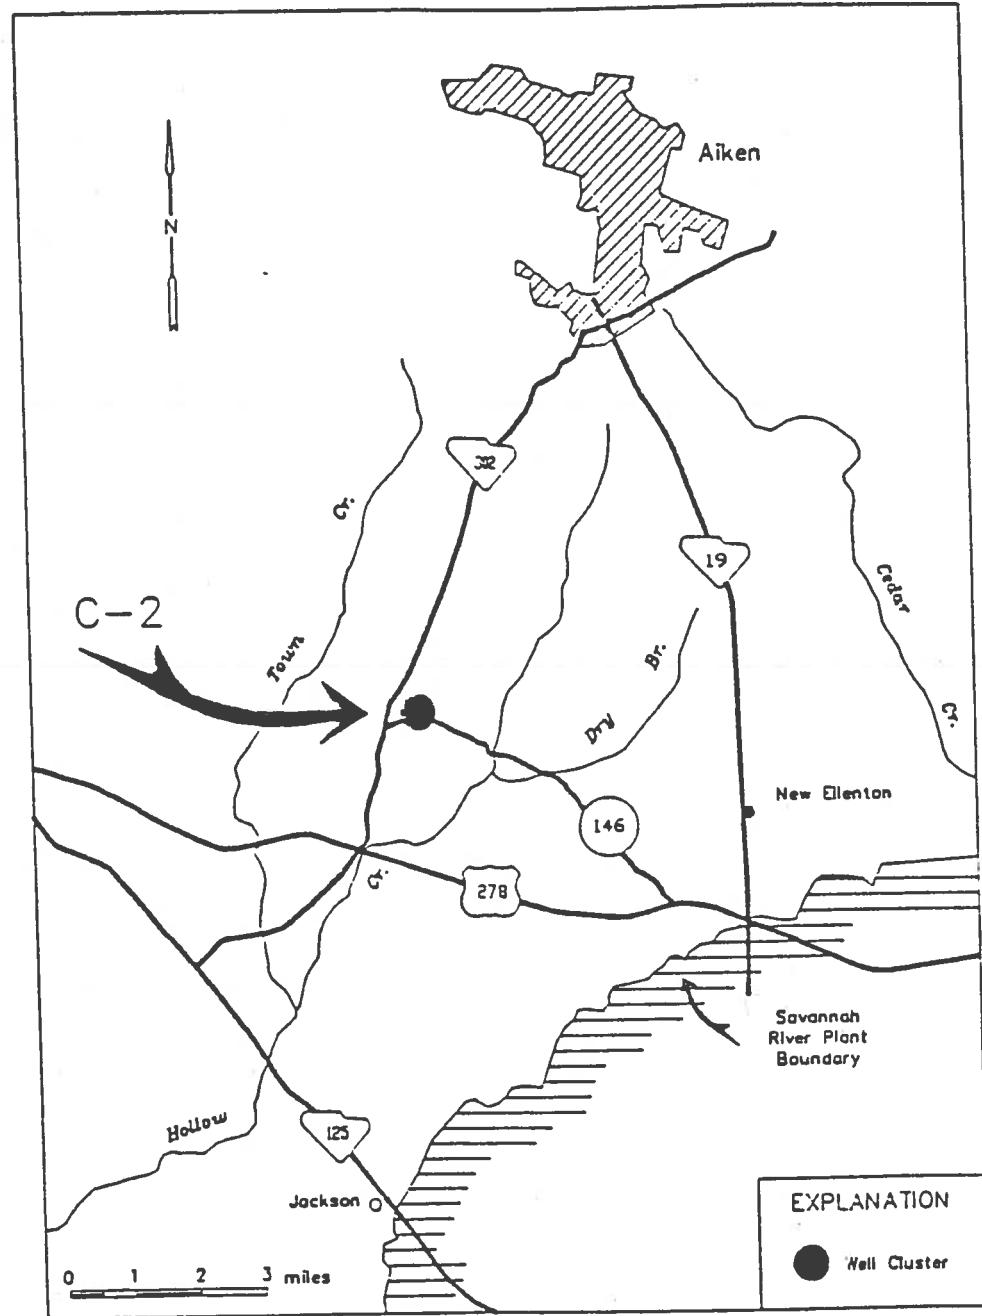

Figure 3. Location of well cluster C-2.

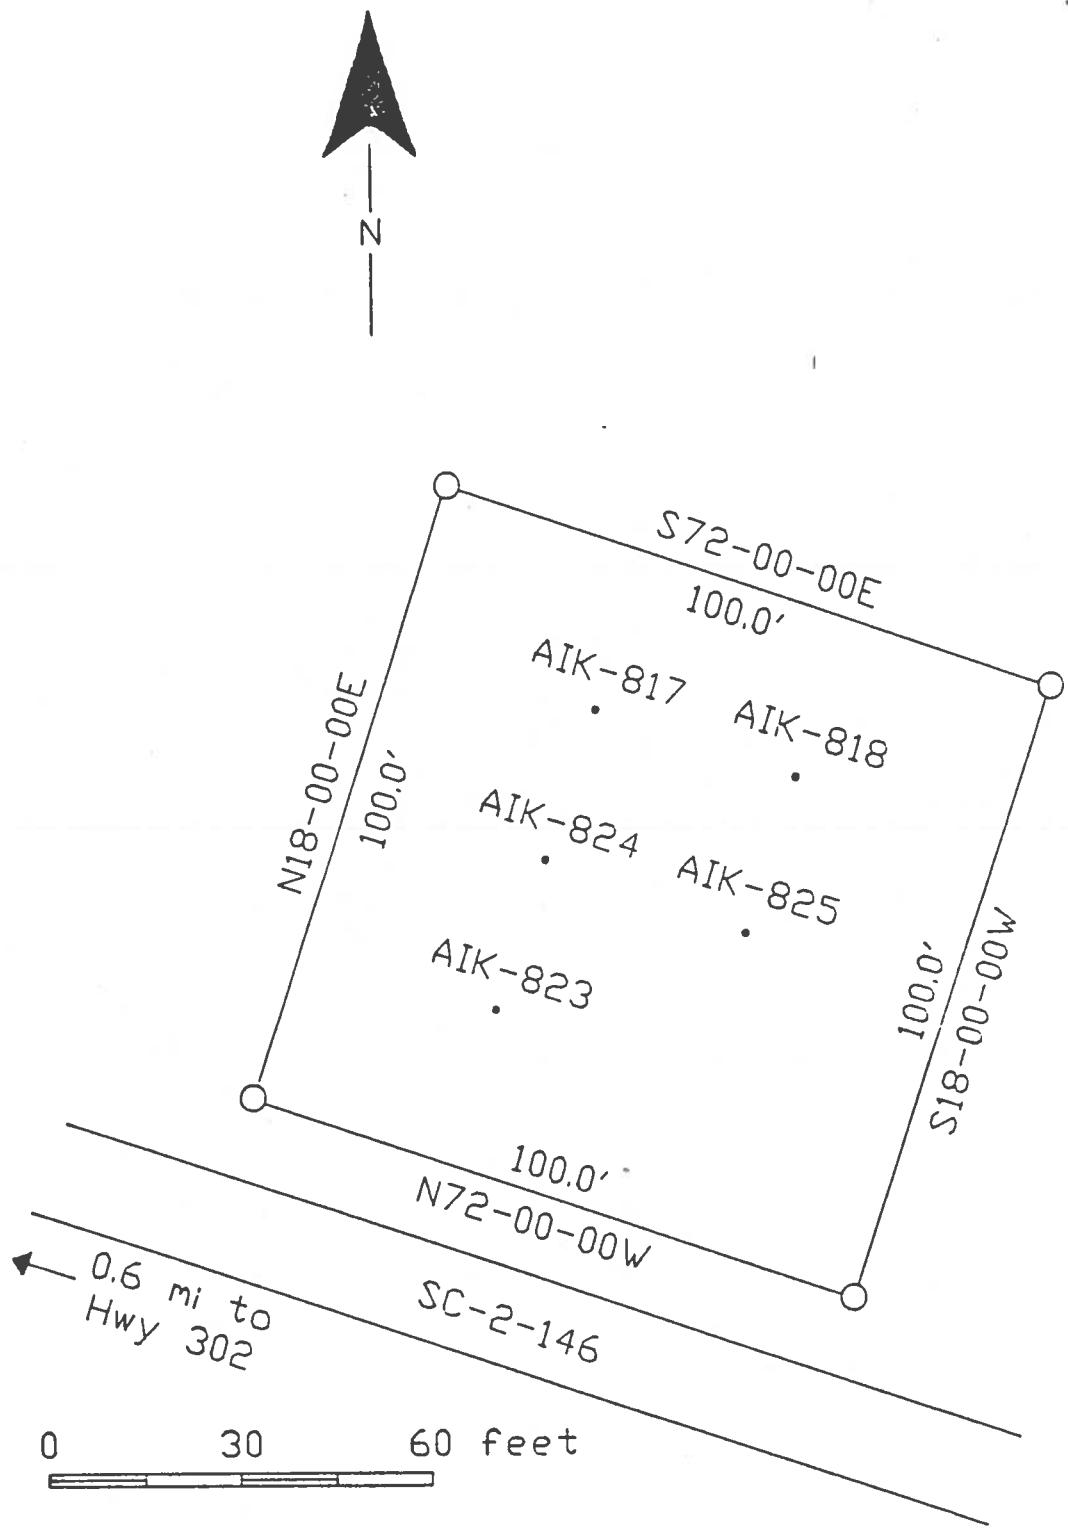

Figure 4. Well cluster C-2 layout.

cluster site C-2 are presented in Figure 5 and again in the Table. In addition, ADR's have been installed on the two Phase I wells, and the entire site has been fenced with 6-ft high industrial 9-gage chain-link fence with a 20-foot gate. For additional information, including a detailed lithologic log and geophysical logs for cluster site C-2, refer to Logan's 1987 Phase I report.

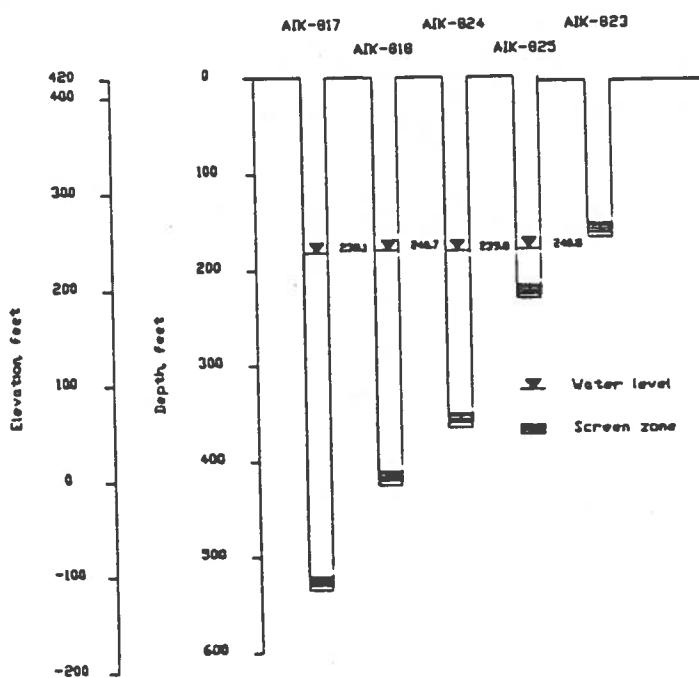

Figure 5. Vertical head relationship for wells at cluster C-2.

CLUSTER SITE C-3

Cluster site C-3 is located about 15 miles east of the city of Aiken, S.C., and within Aiken State Park (Fig. 6). The land elevation is approximately 295 ft m.s.l. Well AIK-826 was installed in the cluster as a part of Phase II activities. The well layout for cluster C-3 is shown in Figure 7.

The exploratory boring (AIK-826) was continuously cored to a depth of 541 ft below land surface (-246 ft m.s.l.). The lithologic column is shown in Figure 8. A detailed lithologic log for AIK-826 is presented in Appendix A. Geophysical logs are presented in Pocket A. Saprolite was encountered at a depth of 520 ft below land surface (-225 ft m.s.l.) and unweathered crystalline rock at a depth of 530 ft (-235 ft m.s.l.). On the basis of data from the deep boring, the screen zone was selected between depths of 485 and 495 ft below land surface (-188 to -198 ft m.s.l.) to best correlate with the deep (Middendorf) monitoring wells at SRP. Complete construction details and the water level measurement are given in the Table and Figure 9.

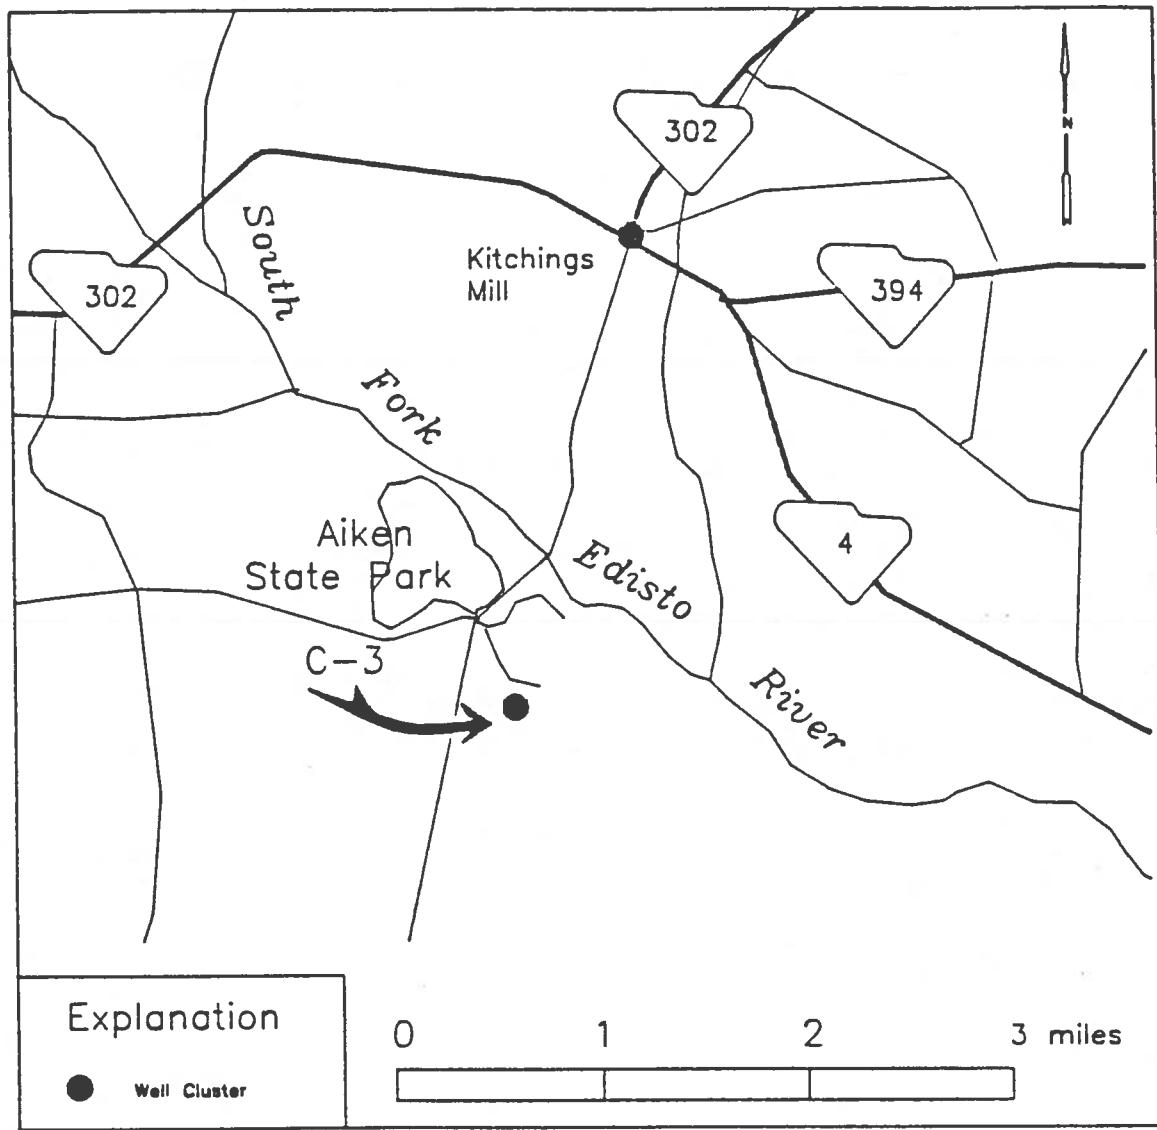

Figure 6. Location of well cluster C-3.

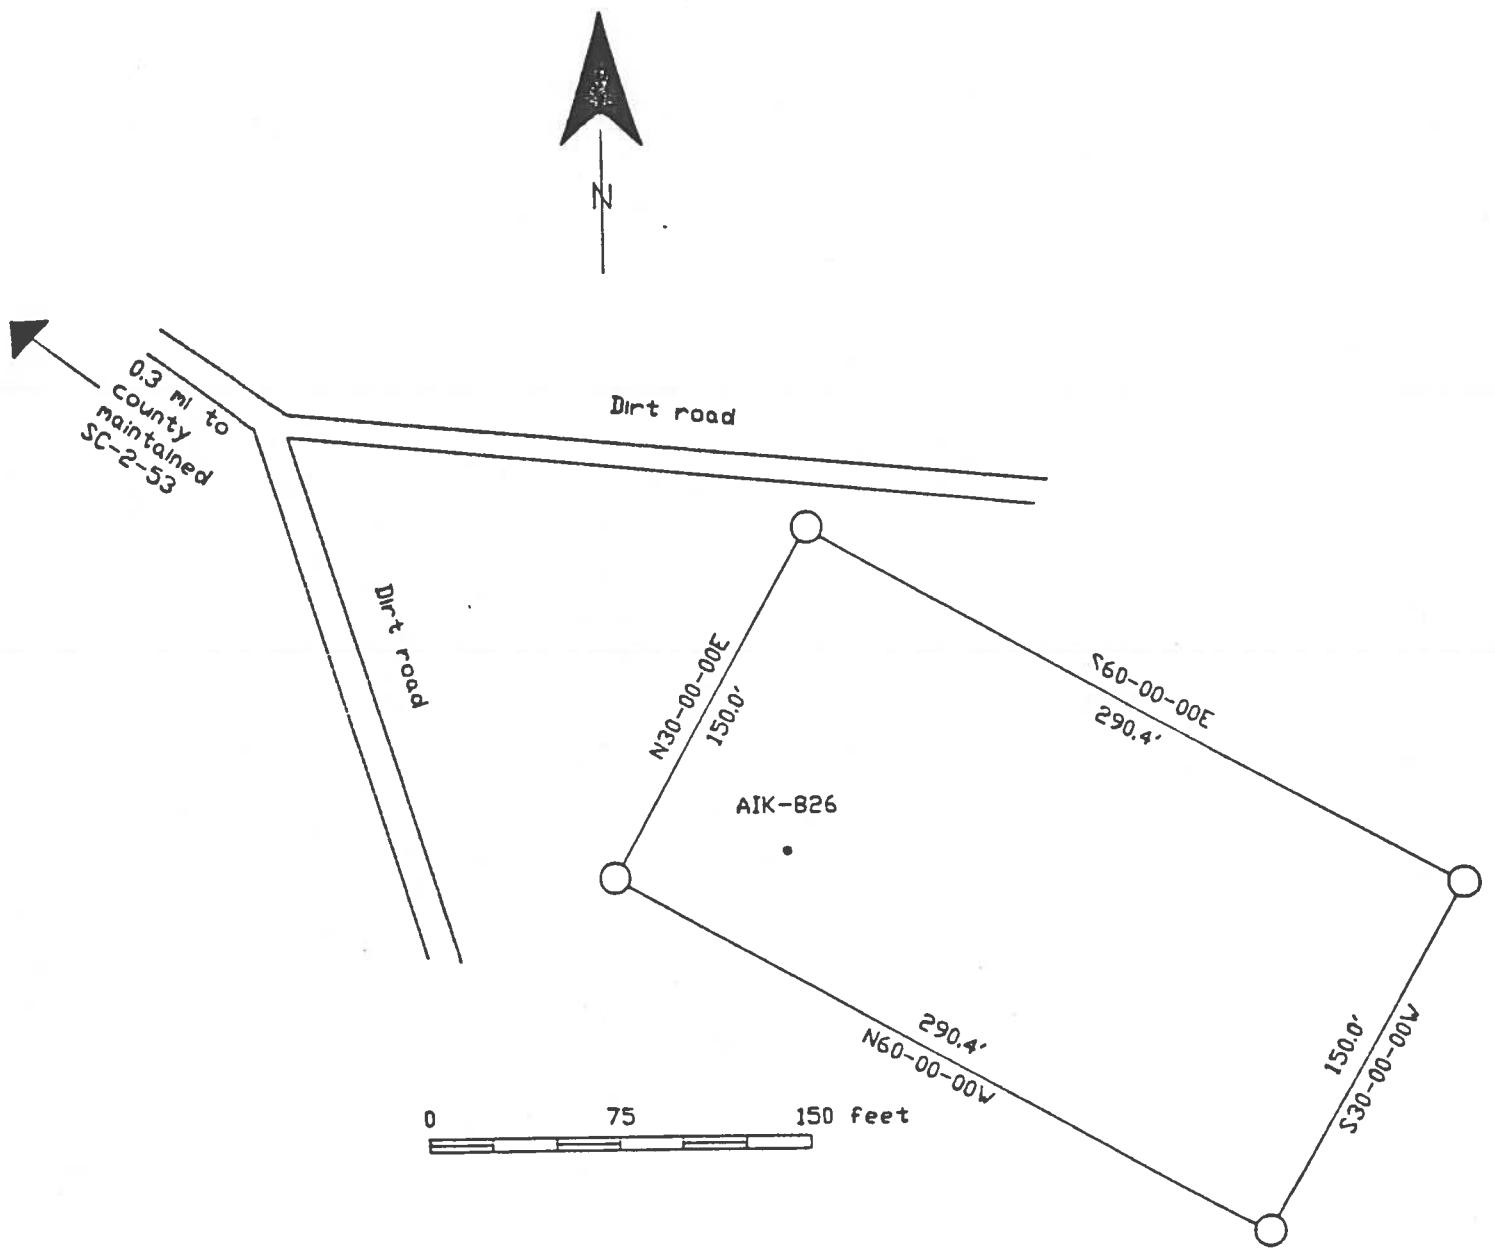

Figure 7. Well cluster C-3 layout.

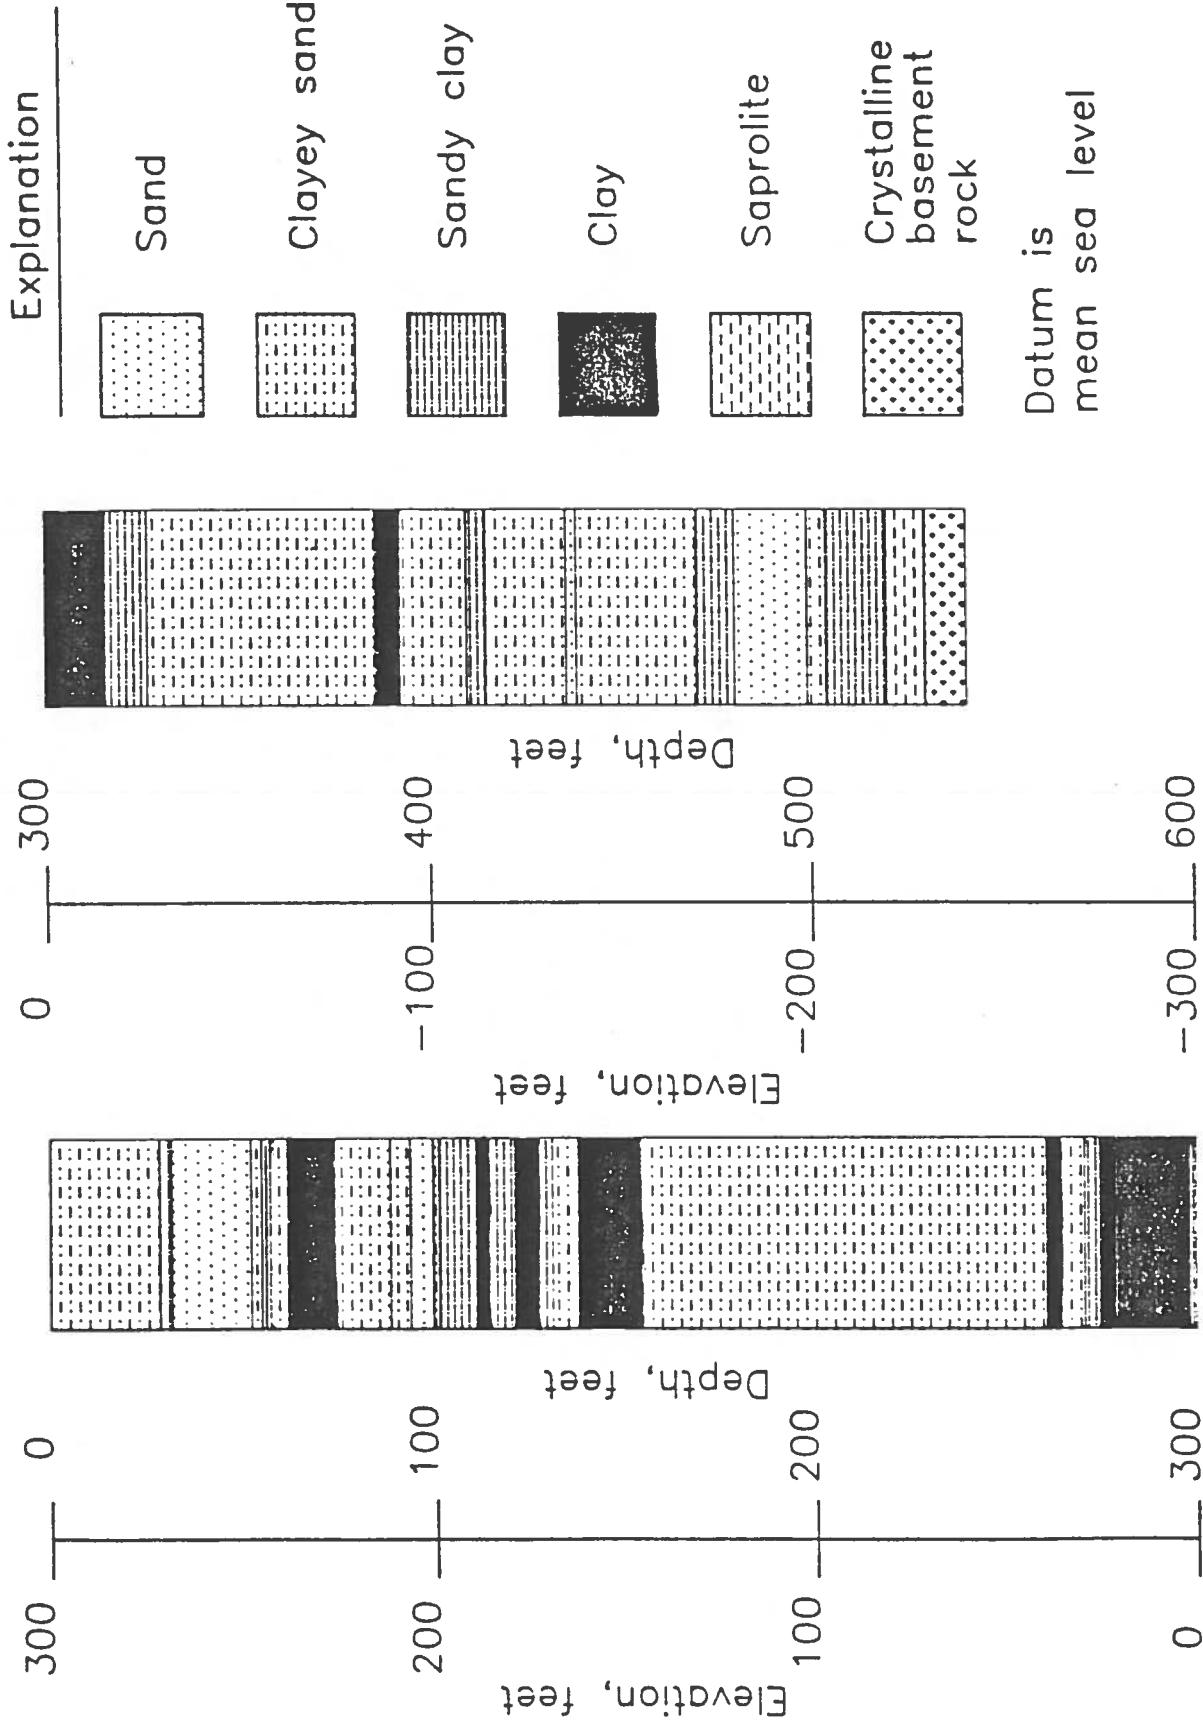

Figure 8. Lithologic column for AIK-826.

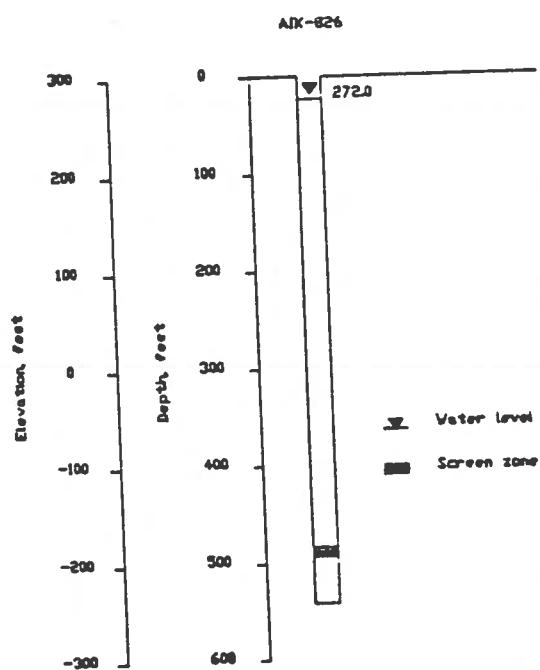

Figure 9. Vertical head relationship for wells at cluster C-3.

CLUSTER SITE C-5

The C-5 cluster site is located about 6 miles northwest of the town of Barnwell, S.C., and 15 miles east of the center of SRP (Fig. 10). The land surface elevation is approximately 265 ft m.s.l. A total of three wells were installed in the cluster as part of Phase II activities. The well layout for cluster C-5 is shown in Figure 11.

The exploratory boring (BRN-357) was continuously cored to a total depth of 1,084.5 ft below land surface (-819.5 ft m.s.l.). Saprolite was encountered at a depth of 1,031 ft (-776 ft m.s.l.) and unweathered crystalline rock at a depth of 1,064 ft (-799 ft m.s.l.). The lithologic column is presented in Figure 12. A detailed lithologic log for BRN-357 is presented in Appendix B and the geophysical logs in Pocket B. Because of difficulties encountered in the removal of temporary casing the exploratory boring (BRN-357) had to be abandoned and plugged with cement. As a result, an offset well (BRN-358) was installed to a depth of 847 ft below the land surface (-582 ft m.s.l.). After examining the lithologic and geophysical logs and consulting with geologists at SRP, the screen zone was chosen between 832 and 842 ft below land surface (-567 and -577 ft m.s.l.). This zone correlates with the "bottom lower Tuscaloosa" of SRP (Middendorf), the deepest zone of the monitoring wells in the cluster-well program. The sediments below the Tuscaloosa are too impermeable at SRP for the installation of a monitoring well. This zone is probably the Cape Fear Formation. Because of the presence of a high permeability zone within the Cape Fear Formation downdip from SRP, it will be screened as a part of Phase III. After examining the data from

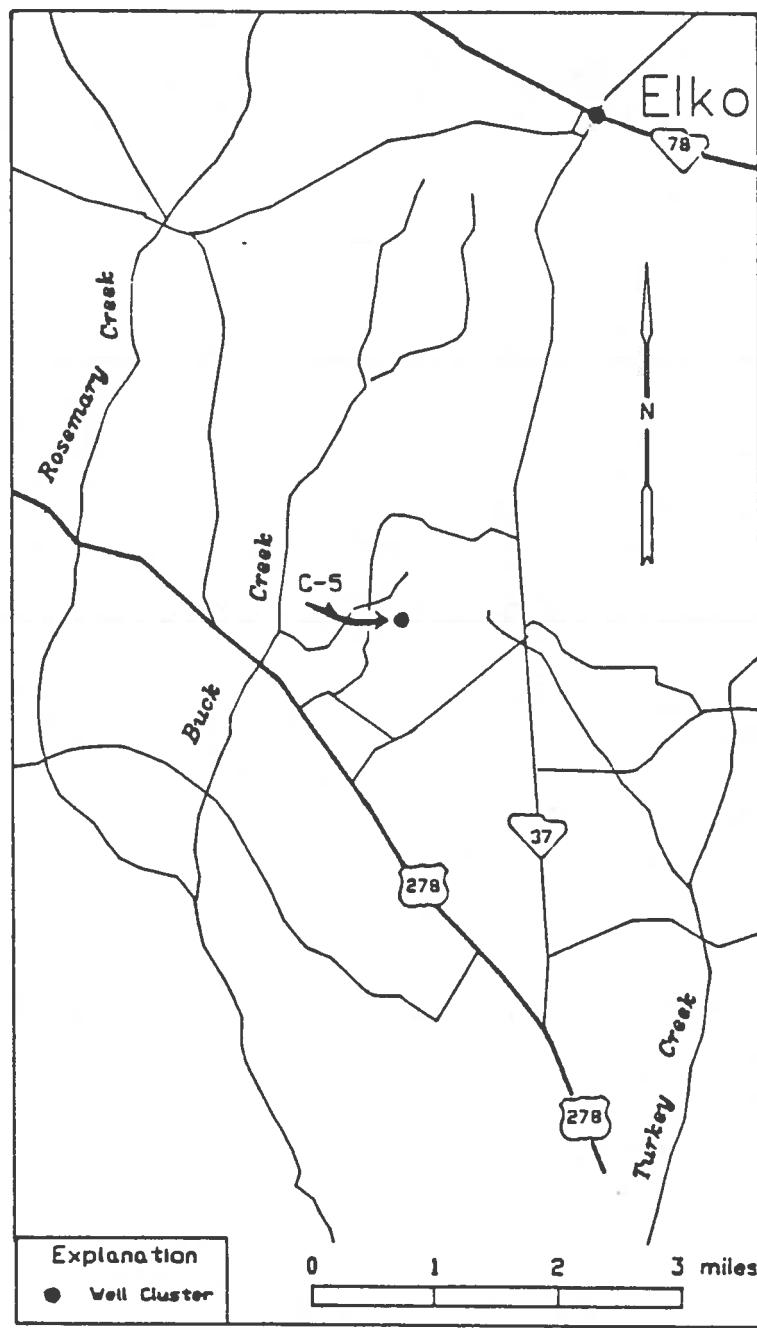

Figure 10. Location of well cluster C-5.

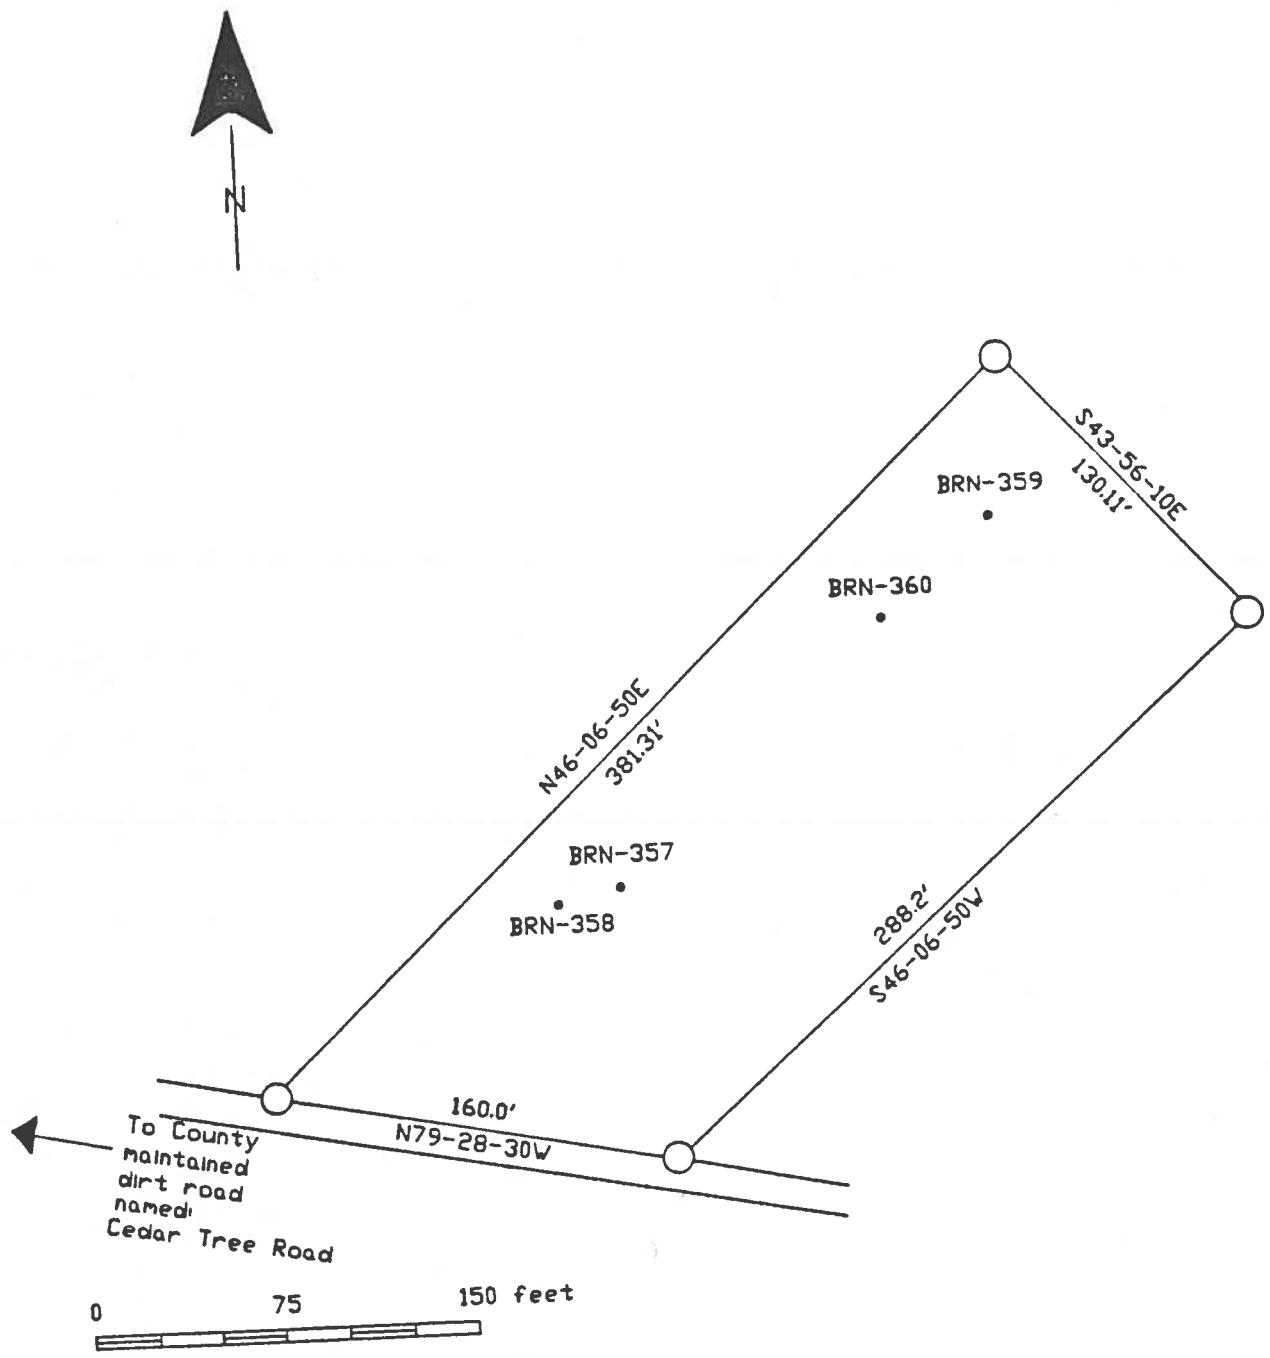

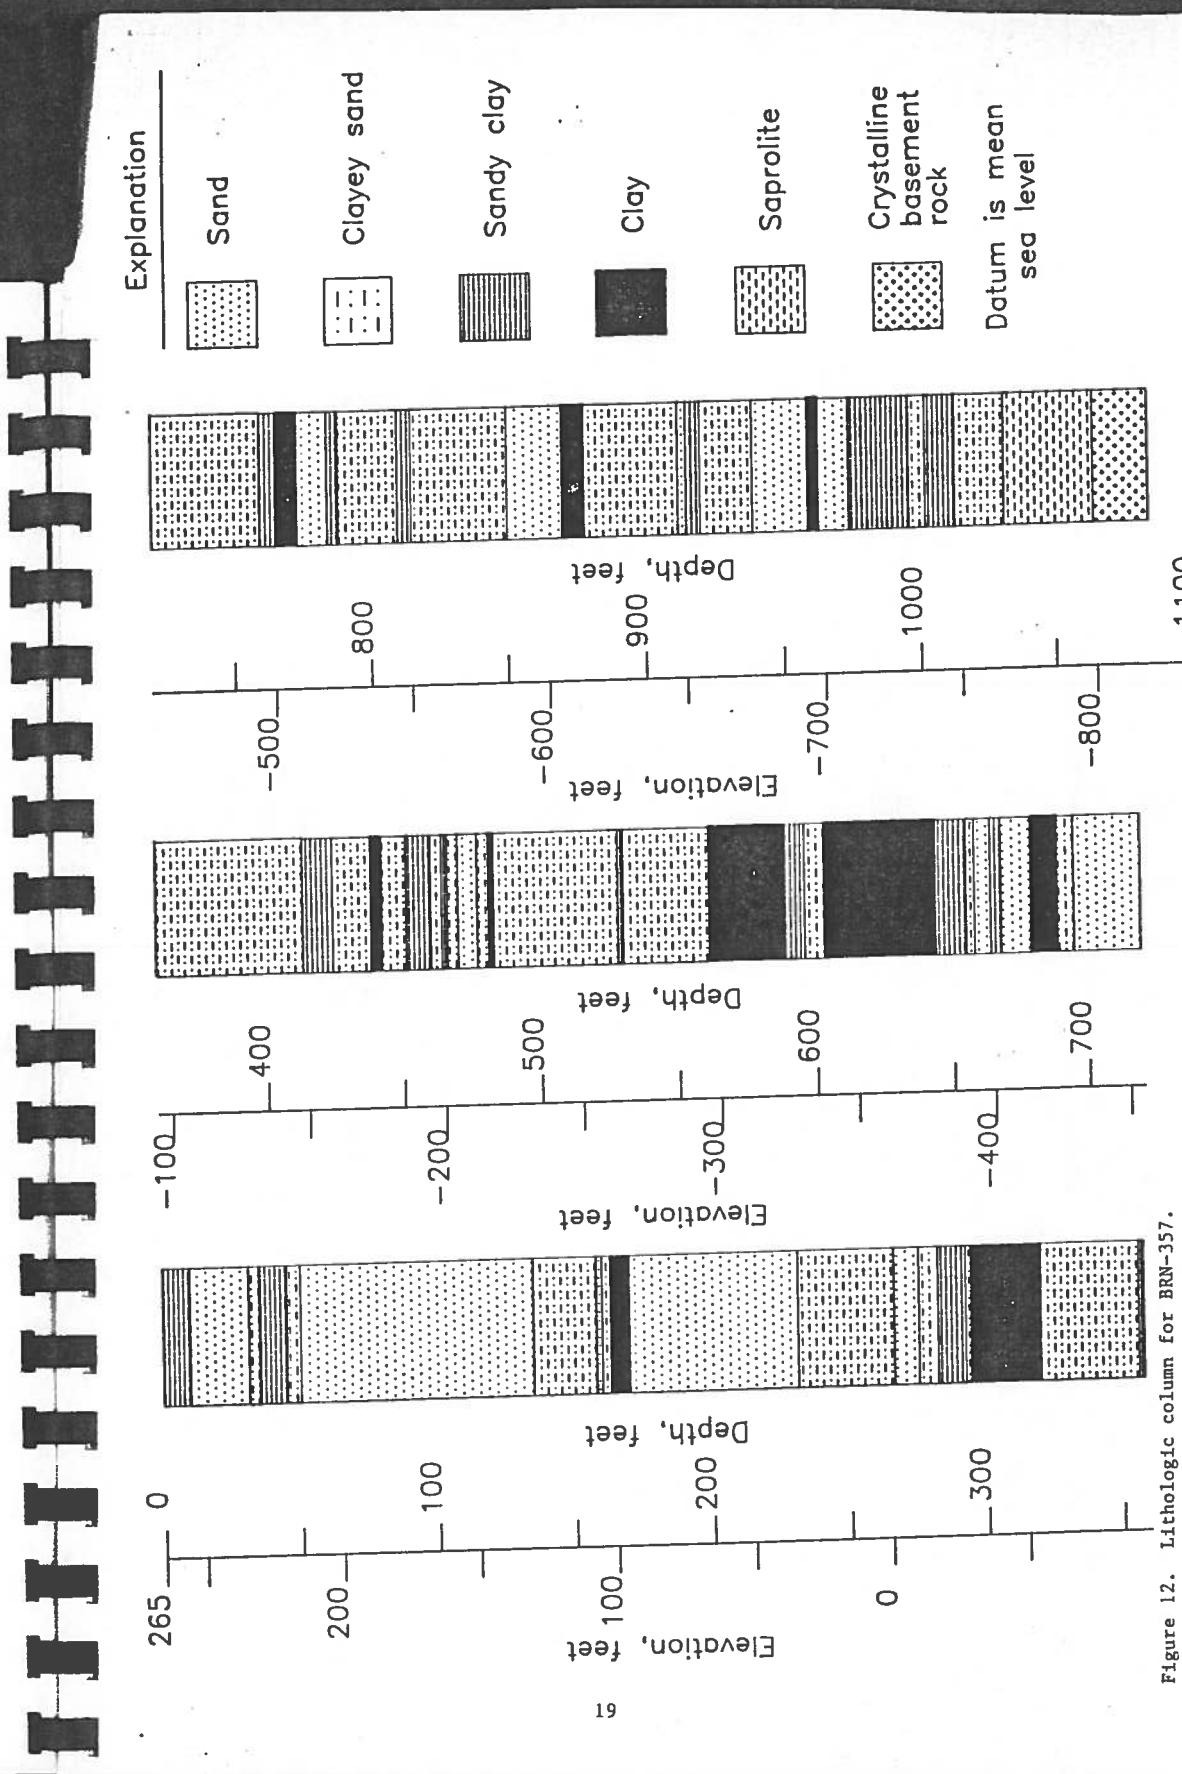

Figure 11. Well cluster C-5 layout.

BRN-357, the screen zones for the two shallowest wells in the cluster were chosen. Well construction data for these wells are given in the Table. The screen zones for wells BRN-359 and BRN-360 were chosen to be 199 to 209 ft and 125 to 135 ft below land surface, respectively (+76 to +66 ft and +140 to +130 ft m.s.l.). Water levels in the three wells are shown in Figure 13.

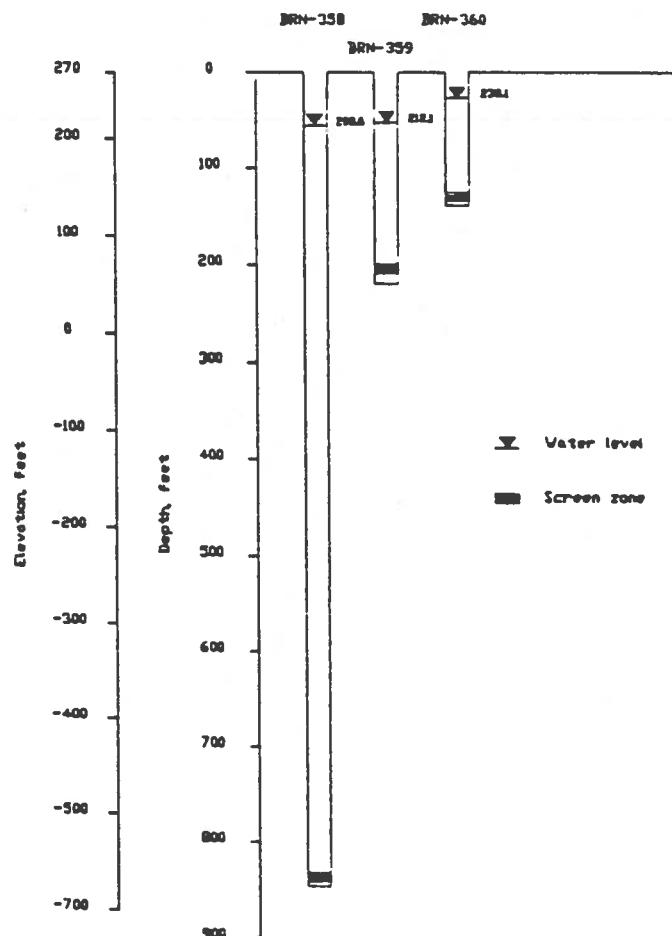

Figure 13. Vertical head relationship for wells at cluster C-5.

CLUSTER SITE C-6

The C-6 cluster site is located about 5 miles southeast of the town of Barnwell, S.C., and 19 miles east-southeast of the center of SRP (Fig. 14). The land surface elevation is approximately 205 ft m.s.l. A total of three wells (BRN-349, BRN-350, AND BRN-351) were installed in the cluster as part of Phase I activities, and five additional wells were installed in Phase II. The well layout for cluster C-6 is shown in Figure 15.

The five additional wells drilled in Phase II are BRN-352, BRN-353, BRN-354, BRN-355, and BRN-356. The first Phase II well (BRN-352) was drilled to a total depth of 295 ft (-90 ft m.s.l.) and screened in the Congaree Formation between 278 and 288 ft (-73 to -83 ft m.s.l.). BRN-353 was drilled to a total depth of 590 ft (-385 ft m.s.l.) and screened in the Peedee Formation between 573 and 583 ft (-368 to -378 ft m.s.l.). BRN-354 was drilled to a total depth of 415 ft (-210 ft m.s.l.) and screened in the Black Mingo Formation between 396 and 406 ft (-191 to -201 ft m.s.l.). BRN-355 was drilled to a total depth of 701 ft (-495 m.s.l.) and screened in the Black Creek Formation between 686 and 696 ft (-481 to -491 ft m.s.l.). The last Phase II well (BRN-356) was drilled to a total depth of 929 ft (-724 ft m.s.l.) and screened in the Middendorf Formation between 914 and 924 ft (-709 to -719 ft m.s.l.). Well construction data and water level measurements are presented in the Table and Figure 16. In addition, a detailed lithologic log and the geophysical logs for cluster site C-6 are presented in Logan's 1987 Phase I report. ADR's have been installed on the three Phase I wells, and the entire site has been fenced

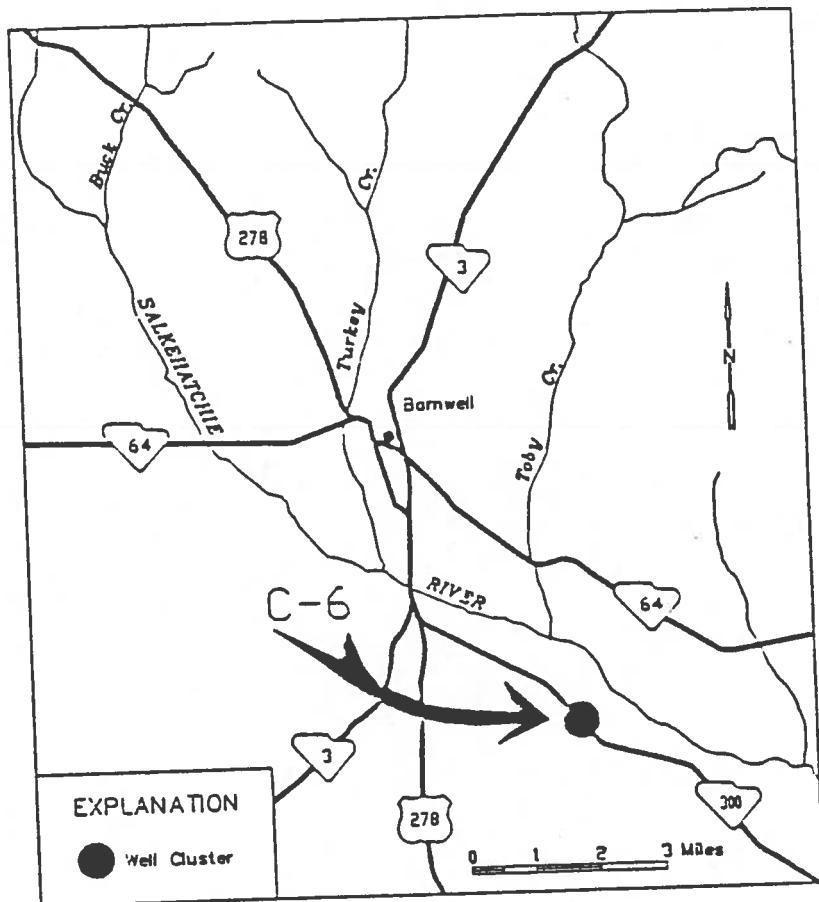

Figure 14. Location of well cluster C-6.

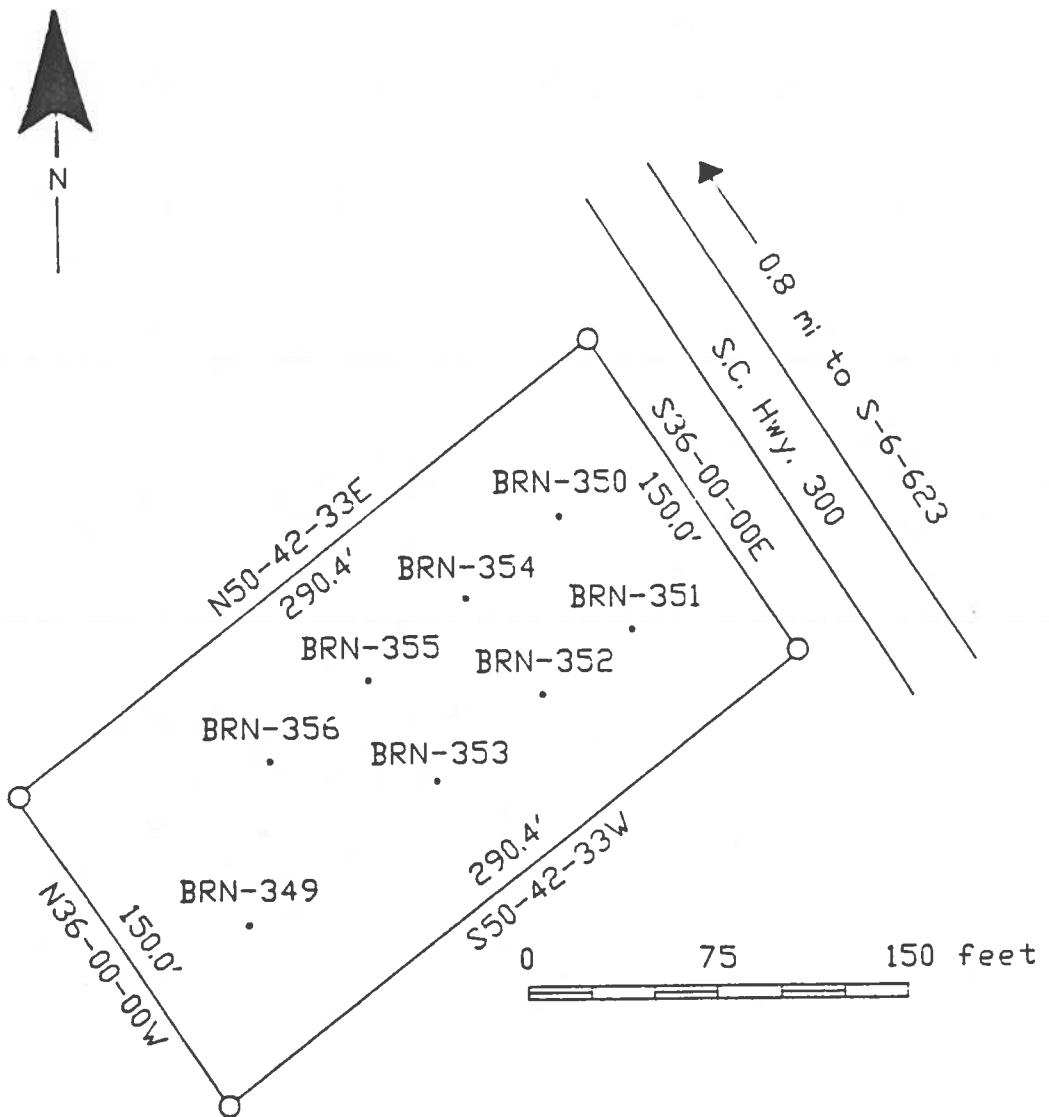

Figure 15. Well cluster C-6 layout.

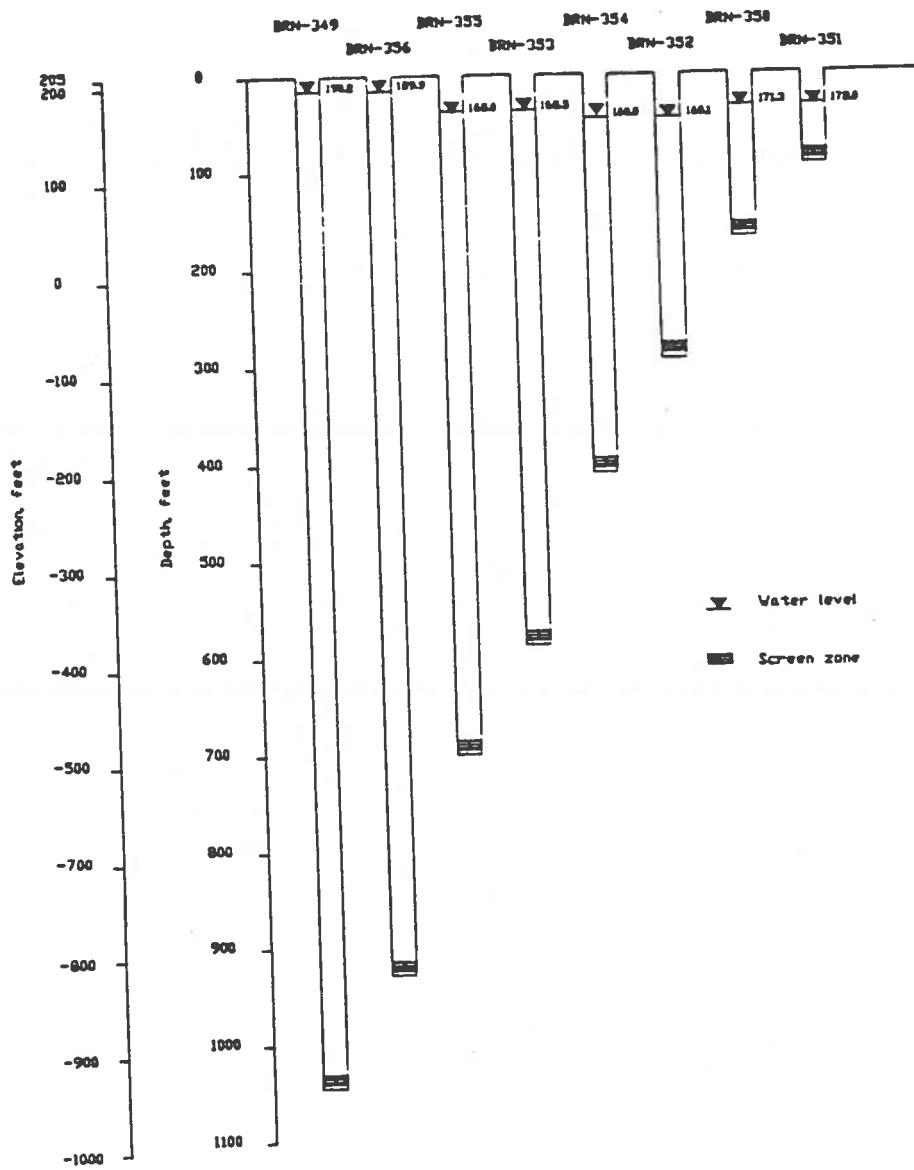

Figure 16. Vertical head relationship for wells at cluster C-6.

with 6-ft high industrial 9-gage chain-link fence with a 20-foot gate. Finally, red cedar seedlings were planted along the perimeter of the compound.

SUMMARY

Phase II of the "Geohydrologic Investigation and Establishment of a Permanent Multi-Observational Well Network in Aiken, Allendale, and Barnwell Counties, South Carolina" project saw the completion of cluster sites C-2 and C-6 as well as the initial coring phase of sites C-3 and C-5. The first well at site C-5 was continuously cored to a depth of 1084.5 feet with a total recovery of 72 percent. Additional coring in an offset well brought recovery up to 78 percent, reasonably good recovery in unconsolidated deposits. Following completion of the core hole, three additional observation wells were completed at the site.

The first well at site C-3 was continuously cored to a depth of 541 feet with a total recovery of 72 percent. Here again, recovery was somewhat low but is reasonable in the unconsolidated sediments. No additional observation wells have been drilled at site C-3 to date. The analytical program for Phase II began in the field with detailed lithologic descriptions of the cores by SCWRC geologists. Further analyses of the cores in the SCWRC geology laboratory will include detailed megascopic and microscopic descriptions, core photography, sieve analyses and insoluble-residue analyses. In addition, the clay fractions from selected intervals will be analyzed by X-ray diffraction.

A team of outside consultants has been selected to provide additional analytical expertise. These consultants were selected on the basis of their experience and their performance with the Savannah River Laboratories so that quality and consistency in the interpretation of the data are assured. The analyses provided by these consultants will include marine macrofossil and microfossil age dating as well as nonmarine age dating by pollen and spores. Further isotopic age dating will be done on pore water and authigenic glauconite grains. Petrographic analyses of thin sections from selected units will be made, and the clay fraction from various aquifers and confining units will be X-rayed to determine the clay constituents. Finally, chemical analyses of water samples from the various aquifers will be made by both the SCWRC water laboratory and outside analysts to determine water type and quality.

The culmination of this in-depth analytical program, coupled with data compiled on SRP by Savannah River Laboratory geologists and hydrologists, will be the most comprehensive and detailed regional subsurface database in the State. This database will in turn give us the necessary tools to further define the complex regional stratigraphy and allow for a full assessment of the water quality, movement, and availability in the region.

Phase III of the project is a cooperative effort between the SCWRC and the microbiologists of the Savannah River Laboratories' "Deep Probe" project. This phase is already under way with the coring of two deep wells at site C-10 near Allendale, S.C., (Fig. 1). During the coring of these wells the microbiologists from the Savannah River Laboratories worked jointly with the SCWRC geologists in developing and applying techniques to collect uncontaminated subsurface samples for

microbiological analyses. Preliminary detection analyses of tracers added to the drilling fluids have yielded very encouraging results, making this project an extremely important step forward in the newly developing field of subsurface microbiology. The second hole on the site is currently being completed in the Cape Fear Formation, making it the first well in the State to be completed in that formation, and thus yielding useful water data for that aquifer. The first well at the site is projected to be screened in either the lower Middendorf aquifer or the Black Creek aquifer. Thus, the two Phase III wells at site C-10 are another crucial step toward reaching the overall objective of gathering high-quality subsurface data so that the hydrogeology of the region can be more fully evaluated.
